observers are (a) natural geometric patterns that develop through the interactions of shapes played out sequentially over time and (b) self-organizing (dissipative) systems. The former group includes polygonal and circular ground patterns, alternating stripes of stones and vegetation, water erosion formations, and so on (see Fig. 1). Among the latter we find examples of water crystals forming on glass, formation of snowflakes, eddies forming in bodies of water, or convection cells (e.g., Bénard cells forming in heated liquids). These are all examples of the second-order emergent phenomena occurring in nature and investigated by specialized subdisciplines of chemistry and physics.

Third-Order Emergents

Finally, scientists distinguish third-order emergent phenomena as resulting from interactions sensitive to shape and time that show heritable and teleological features. As examples we can list feedback control systems, homeostatic processes, the origin and organization of life (from subatomic level to the entire biosphere), and various cases of swarm behavior (ant and bee colonies, migrating insects, schooling fish, flocking birds, etc.).

Still Higher Orders of Emergents

However, the science of EM does not stop on this standard three-order classification of emergent phenomena. Going back to the bottom level of complexity, the physics of quantum mechanics seems to suggest that quantum entanglement and our perception of a deterministic reality – in which objects have definite qualitative features, positions, momenta, and so forth – are both emergent phenomena, grounded in the true state of matter described by a wave function, which does not allow us to assign to elementary particles definite positions or momenta. A similar situation obtains with the laws of physics as we know them today. It is believed that they all emerged from one fundamental law, which is yet to be found by science. Moving up on the scale of complexity, one may argue that the laws of chemistry emerged from those of physics and gave the origin to the laws of biology (including evolution). The laws of biology provided, in

Emergence, Fig. 1 Circles of stones (Svalbard Archipelago in Norway) – an example of emergent phenomenon occurring in nature (Hannes Grobe, “Permafrost Stone-

Rings,” Wikipedia, August 31, 2007, https://en.wikipedia.org/wiki/File:Permafrost_stone-rings_hg.jpg).

turn, a necessary foundation for the EM of the laws related to human mind, consciousness, mental states, qualitative feels, conceptual representations, rationality, and language – the object of study in psychology, social sciences, and linguistics.

Acceptance of this argument opens a way to consider as emergent a number of other familiar phenomena, such as spontaneous organizational tendencies characterizing groups of people, economic trends and the stock market, architectural and traffic patterns of modern cities, the World Wide Web, patterns of Internet traffic (including patterns in the social media), and so on. These are all examples of decentralized complex occurrences exhibiting higher-order irreducible emergent properties.

Basic Characteristics of Emergence

There have been many attempts at defining fundamental doctrines and philosophical commitments of EM theory (e.g., Kim 2006; Clayton 2004; Peterson 2006; Humphreys 2016). Their comprehensive list involves at least eight central aspects.

Nonadditivity of Causes

The first formulation of EM came with Mill’s distinction of the physical (based on mechanics) composition of causes – referring to the vector or algebraic addition – from the chemical mode of combined action of causes. Because products of chemical reactions are not simply algebraic sums of the effects of each reactant, Mill suggested

calling them “heteropathic effects.” He distinguished them from “homopathic effects” applicable in physical mechanics (Mill 1846, 212). If this is the case in cause-effect interactions in chemistry, concluded Mill, then the causal effects distinctive for living systems must be nondeducible from those characteristic of their chemical ingredients all the more. Lewes, who used a slightly different terminology of “resultant” and “emergent” effects, distinguished the latter as incommensurable and irreducible to the sum of their components.

Novelty of Emergent Processes, Entities, and Properties

An acknowledgment of the reality of heteropathic/emergent effects leads to an attempt to define the ontological nature of emergents more precisely. The three most popular ontological categories mentioned in this context are (1) emergent processes (events), (2) emergent entities (substances), and (3) emergent properties (qualities).

Ontological Monism and Qualitative Difference: Nonreductionist Physicalism

Contemporary emergentists seem to accept ontological monism, saying that “all individuals are constituted by, or identical to, micro-physical individuals, and all properties are realized by, or identical to, micro-physical properties” (Gillett 2003, 28). At the same time, they emphasize the novelty and qualitative difference of emergent properties, which cannot be instantiated simply by quantitative accumulation of the basic constituents of material entities and/or their properties. Their position is oftentimes classified as a non-reductionist version of physicalism.

Emergence and Mereology

Understood in terms of the qualitative novelty of emergents, which, nonetheless, are realized by the most basic material constituents, the theory of EM classifies as mereological. Its main objectives are built around structural and dynamical dependencies between the wholes and their parts. What is being emphasized by the proponents of EM is both the necessity and insufficiency of parts for

the existence of the whole. The claim of necessity strives to protect the emergentist position from dualism, while the claim of insufficiency contrasts it with reductionism.

Levels of Organization

The fact that EM is grounded in ontological monism and mereology requires from it a theory and language describing the hierarchy of various stages of organization of the constituent parts of emergents. The language of levels of organization was first introduced by Alexander in the second volume of his *Space, Time and Deity*, where he says: “The higher-quality emerges from the lower level of existence and has its roots therein, but it emerges therefrom, and it does not belong to that lower level, but constitutes [in] its possessor a new order of exist[ence] with its special laws of behavior” (Alexander 1920, 2:46). More recently, a group of researchers led by Claus Emmeche proposed a more thorough ontological specification and classification of levels of complexity, emphasizing their physical interdependence and metaphysical “inclusivity” (Emmeche et al. 1997).

Emergent Laws

Another characteristic feature of emergent phenomena is that their scientific description leads to the discovery of new laws of nature, unique and specific for higher levels of complexity. Acknowledging this fact, Mill – contrasting homopathic and heteropathic effects – concludes that the latter are governed by new, heteropathic laws. Alexander speaks about new laws ruling the emergents, whereas Broad analyzes emergents in terms of “trans-ordinal laws,” which he defines as laws connecting “the properties of aggregates of adjacent orders” and which he differentiates from “intra-ordinal laws” connecting the properties of aggregates of the same order (Broad 1925, 77–78). Clearly, the status of the laws of nature is widely debated in the philosophy of science (see Carroll 2016). Many do not assign to them an ontological character of any kind and see them as descriptive rather than prescriptive. But even if they simply describe the results and effects of the activity of emergent entities and dynamical

systems, they are real features of the world and thus might be considered as important indicators of EM.

Nondeducibility, Nonpredictability, and Irreducibility of Emergents

Taking into account all aspects of EM discussed so far, it becomes apparent that it can be further characterized in terms of another three essential characteristics, i.e., nondeducibility, nonpredictability, and irreducibility of emergent entities, properties, and laws.

First, deducibility – understood as deriving a conclusion from something already known – is not applicable to emergents. For emergents – for instance, emergent laws – are brute nomological and nonderivative facts which, according to Broad, must “simply be swallowed whole with that philosophical jam which Professor Alexander calls ‘natural piety’” (Broad 1925, 55).

Second, predictability – defined as envisaging future states of affairs – is also impossible in case of emergents. It is true not only because the occurrence of hierarchical levels or layers and relations between them depend on the fundamental indeterminism of the physical universe. The ontological nature of emergents is such that, even if we are able to form emergent laws inductively, we are not able to make the same kind of prediction about the EM of a possible new property of the already known kind theoretically.

Third, emergents are resistant to reduction, which Ernest Nagel defines in terms of a situation in which “the experimental laws of the secondary science (and if it has an adequate theory, its theory as well) are shown to be the logical consequences of the theoretical assumptions (inclusive of the coordinating definitions) of the primary science” (Nagel 1961, 352). He claims reduction covers both homogenous cases (simple and direct intertheoretical reduction) and non-homogenous cases (more complex and indirect reduction that introduces a middle step engaging bridge laws). It is being said that the scientific account of emergents resists both versions of Nagel’s reductionist program and Kim’s suggestion that emergent properties are reducible when they can be functionalized, i.e., construed or reconstrued by their causal/nomic relations to lower-level

properties of a given dynamic system S (see Kim 1999, 9–18, Humphreys 2016, 197).

Emergence and Downward Causation

The irreducibility of emergents is usually related to their causal contribution to ongoing processes of the world. Indeed, many treat the question concerning what emergents can actually “do” after having emerged as pivotal for the whole theory of EM. For without having causal powers, emergent properties would simply turn out to be epiphenomenal and, as Alexander says, “undoubtedly would in time be abolished” (Alexander 1920, 2:8). Consequently, the final characteristic of EM, and as it turns the one of an ultimate importance, must be that “Emergent properties have causal powers of their own—novel causal powers irreducible to the causal powers of their basal constituents” (Kim 1999, 22).

These novel causal powers are usually given the name “downward causation” (DC) (some philosophers refer to downward- or macrodetermination). Unlike upward causation (an instantiation of a higher-level property by a lower-level property) and same-level causation, DC occurs when an emergent higher-level property causes (has an influence on) the instantiation of a lower-level property (Campbell 1974, 180). An example of DC that is often brought and hotly debated in most recent philosophy of mind is the causal influence of mind on the brain – out of which it emerges – and on the activities of the entire human organism.

The power of the concept of DC lies in it providing an answer to the apparent insufficiency of the compositional explanation of complex higher-level entities encountered in nature and investigated by natural sciences. At the same time, however, DC triggers a detailed and nuanced philosophical analysis and debate, related to the one concerning types (species) of EM (see Paolini Paoletti and Orilia 2017a; Tabaczek 2019).

Species of Emergence

Although the list of basic characteristics of EM speaks in favor of the clarity and the metaphysical sharpness of the theory, the truth is that EM is not, in fact, an unambiguous term. Quite contrary,

Emergence, Fig. 2 Types of emergence

studied and analyzed from different perspectives, within different subdisciplines of science and philosophy, and in reference to a variety of phenomena on different levels of complexity, EM becomes, in a way, a term of family resemblance. One of the most basic distinctions within the theory itself classifies certain phenomena as ontologically emergent while other phenomena as irreducible and emergent merely epistemologically. Moreover, it turns out that the ontological novelty of emergents can be defined in several different ways. Hence, a classification of various types of EM may be offered, as depicted in Fig. 2 (see Chalmers 2006; Peterson 2006).

Epistemological and Ontological Emergence

The crucial distinction that needs to be mentioned is the one between the epistemological (weak) and the ontological (strong) versions of EM. The former, weak type of EM, is perceived as an outcome of natural limitations in human analytic possibilities, knowledge, and understanding. Because these limitations are not unsurpassable, we can expect that, with the development of our cognitive skills and research methods, what today classifies as irreducible and emergent (and corresponds with the list of basic characteristics of EM discussed above) will find reductionist explanation in the future. This kind of EM is differentiated from strong EM, which assumes that emergent phenomena belong to the fabric of the universe and are thus intrinsically irreducible. The ontological version of EM, however, requires a more precise specification of the metaphysical and ontological novelty of emergents, which may put it in conflict with physical monism and physical causal closure.

The literature on EM offers at least three ways of defining ontological novelty of emergents.

Downward Causation-Based Ontological Emergence

The first (1) and most popular way of defending ontological novelty of emergents refers to the concept of downward (top-down) causation. Its advocates find it decisive for the formulation of the general rule concerning qualitative difference of emergents from their basal constituents. They argue that despite emergents' physically monistic foundations, due to the novel and irreducible character of DC, emergents remain free from the charge of epiphenomenalism and resist reductionist programs in science and philosophy of science.

However, downward causation-based EM faces the difficulty of specifying both causal relata and the very nature of causation in question (Hulswit 2006; Tabaczek 2019). Its supporters face a critical dilemma, namely, the struggle between supporting the rule of physical causal closure and acknowledging the novelty and irreducibility of DC. The former presupposition, referred to as the causal inheritance principle, states that causal powers on higher levels of complexity are always a "product" of the causal powers of the basal properties on lower levels of complexity and thus must belong to the same ontological category. The latter argument in favor of the ontological novelty of DC seems to suggest the opposite. This dilemma is closely related to the struggle of reconciling ontological monism and the qualitative difference of emergents (see the third characteristic feature of EM listed above). It was probably best expressed by Kim's famous argument from causal exclusion (Kim 1999, 31–33), in which he shows – on the example of mental causation arising from neural patterns – that the argument in favor of DC involves causal overdetermination, i.e., the same mental state is caused by both lower-level neural patterns and DC. He claims the latter must be excluded, which consequently makes the whole project of EM fall into physicalism.

Kim's argument triggered a hot debate which still continues within the circles of philosophy of mind and philosophy of science (see an overview of this debate in Paolini Paoletti and Orilia 2017b;

Tabaczek 2019, 78–91). One of the important arguments defending irreducibility of DC suggests it should be redefined in terms of Aristotle’s plural typology of causes, especially in reference to his notion of formal and final causes (teleology) (Emmeche et al. 2000; Silberstein 2006; Moreno and Umerez 2000). An attempt at realizing this postulate, in the context of both the classical and the contemporary neo-Aristotelian metaphysics, was offered in Tabaczek 2019 (247–270).

Whole-Part Constraints-Based Ontological Emergence

The other two, alternative ways of defending ontological novelty and irreducibility of emergents concentrate, respectively, (2) on the idea of natural systems’ growing complexity due to external constraints and (3) on the theory of supervenience (SUP). The constraints considered in (2) can be defined either (2a) non-causally (Gillett 2003, 42, Juarrero 1999, 132–133, Campbell 2015) or (2b) causally, i.e., in terms of “causation of absences” (Deacon 2006, 143, Deacon 2012, 194–195). In both cases “emergent properties are not something added, but rather a reflection of something restricted and hidden via ascent in scale due to constraints propagated from lower-level dynamical processes” (Deacon 2012, 203) – which protects the theory of EM from the charge of causal overdetermination. What rises questions in whole-part constraints-based ontological EM is the ontological status of constraints in (2a) and the nature of causation attributed to them in (2b) (see Tabaczek 2019, 120–125).

Supervenience-Based Ontological Emergence

Concerning (3), SUP – which provides one of the most popular explanations of mind/brain dependency – is defined in terms of simple covariance between two types of properties: “A set of properties *A* supervenes upon another set *B* just in case no two things can differ with respect to *A*-properties without also differing with respect to their *B*-properties. In slogan form, “there cannot be an *A*-difference without a *B*-difference” (McLaughlin and Bennett 2014).

However, when analyzed within the context of emergentism, SUP is said to entail not only metaphysically neutral covariance between physical and emergent but also their nonidentity, dependence, and

directionality, all three having an ontological dimension. If this is the case – the argument continues – SUP becomes a possible metaphysical foundation for ontological EM. Without introducing physically novel entities and causes (DC), the fact of non-identity, dependence, and directionality of supervenient properties on their subvenient basal property counterparts suffices to build upon it a SUP-based theory of ontological EM.

Challenging this proposition, a number of emergentists emphasize a radical difference between SUP and EM, which puts in question the plausibility of the SUP-based version of ontological EM. Humphreys suggests that SUP is acceptable merely as a consistency condition, enabling attribution of concepts concerning properties characteristic for different levels of complexity, whereas EM provides an explanation of ontological relationships between them (Humphreys 1997). Kim says the question of what must be added to covariation to yield dependence remains an interesting and deep metaphysical query for which there is no easy answer (Kim 1990).

Conclusion

These somewhat technical distinctions and conversations concerning characteristics and species of EM are not trivial. For while we are fascinated with the remarkable beauty and paradoxical regularity and simplicity of emergent processes, entities, and properties – originating within higher orders (levels) of complexity of matter (oftentimes out of chaotic behavior of its basic constituents) – we realize that understanding and harnessing the fundamental organizing principles, as well as the theoretical basis of emergents, remains one of the grand challenges of the joint effort of natural science and philosophy.

The question of whether there are any instances of ontological EM remains controversial. Some metaphysicians and philosophers of mind – based on first-person, introspective grounds – contend that consciousness, intentionality (free will), and human agency are ontologically emergent (Hasker 1999; O’Connor 2000). Various authorities in natural sciences such as the Nobel laureate chemist Ilya Prigogine and, more recently, Nobel laureate

in physics Robert B. Laughlin claim that, respectively, “the dissipative structures of non-equilibrium thermodynamics” and properties of certain kinds of macroscopic matter such as crystalline states, which are insensitive to their microscopic constituents, classify as cases of ontological EM (Nicolis and Prigogine 1977; Laughlin and Pines 2000). However, many other scientists and philosophers dismiss such claims and declare that if EM is real, it is merely epistemological. The research and discussion concerning the nature and the metaphysical status of EM continues.

Nevertheless, no matter what the final conclusion in this debate will be (assuming it is possible to reach one), EM theory as such is rightly considered as one of the major conceptual tools in our attempts to understand and define both the origin and the actualization of new potentialities and possibilities. For those who interpret emergents ontologically – especially within the context of the classical and neo-Aristotelian philosophy – the notion of EM helps to discover, describe, and classify the vastness of the scope, depth, and fecundity of potentialities inherent in the universe we live in. They see possibilities characterizing more basic levels of organization of matter as being actualized on qualitatively different, higher (emergent) levels of organization, whose nature reveals, in turn, new ranges of possibilities that may come into realization within still higher orders of both physically and metaphysically conceived complexity. According to them, this nested hierarchy of interdependent and complementary orders of potentiality (possibility) and actuality grounds ontologically all entities and phenomena observable in the universe. Even those who find EM as a merely epistemological category do acknowledge its importance as a source of an intellectual inspiration and incentive to analyze the reality across the scales and orders of magnitude and quantity of objects that constitute it.

Emergentism

Gil Santos

Universidade de Lisboa, Faculdade de Ciências,
Universidade de Lisboa, Lisboa, Portugal

Abstract

Emergentism is the view that there are certain real-world entities necessarily generated from and constituted by other entities but not fully reducible to them ontologically and/or epistemically. Emergence is thus a relation in which an entity (the “emergent”) is partially dependent on and partially independent of the entities with respect to which it is said to be emergent (the “emergence base”). The emergence bases provide the necessary but not sufficient conditions for the emergents’ existence or identity. Ontological emergence occurs when some real-world entity, such as an object, process, property, causal power, or law, is

not fully (pre)determined or generated by its respective base entities. Epistemological emergence occurs when some real-world entity cannot be represented, predicted from, or explained by concepts, theories, law-statements, or models referring to its respective base entities. The emergence relation can be further conceived diachronically, as a process, and synchronically, as a distinctive ontic status. In the first case, emergence refers to the relation between a newly formed entity and its original emergence base, or to the relative independence of certain macro-properties of a system relative to many changes in its parts' properties. In the second case, emergence refers to the emergent status of a system in virtue of its qualitative difference and relative causal autonomy, at any time of its development, vis-à-vis the properties and causal profiles of its contemporary parts. Finally, some emergentists also claim that ontologically emergent systems causally affect, constrain, control, or condition their own parts' identities or behaviors.

Emergence · Reduction · Explanation · Micro-determinism · Predeterminism · Downward causation · Causal powers · Possibility

History

Emergentism was born in the attempt to answer the following question: How can we make sense of the generation of new real-world entities instantiating new and somehow irreducible properties, causal powers or laws, while assuming the fundamental unity of the world and the causally continuous process of its evolution?

With the goal of overcoming both reductive physicalisms and non-naturalistic ontological pluralisms, the term “emergence” was first used by a group of British philosophers in the late nineteenth century. According to reductive physicalism, any entity either belongs to the fundamental physical level of reality or is completely reducible to it, as a mere epiphenomenal by-product. According to non-naturalistic pluralism, all levels

of reality (matter, life, mind, etc.) are to be taken as equally real, but the higher levels' existence can only be fully explained by appealing to extra-natural principles, substances or forces, such as souls, *entelecheia*, *élans vitaux*, or divine agencies (Morgan 1923, pp. 2, 8–9, 12; Broad 1925, pp. 56–58, 84–90). Against both these views, the first Emergentists tried to reconcile monism with pluralism by defending that qualitatively different levels of reality can come into existence by virtue of certain relational processes involving only lower-level natural entities and processes. Analogously, they tried to conciliate the continuist and discontinuist views of evolution, by defending the existence of processes of qualitative differentiation and generation of novelty within a causally and quantitatively continuous view of the evolutionary process. Emergentism cannot admit causal breaks, leaps, or gaps in Nature (Morgan 1923, p. 5, 39). In Lewes (1875, pp. 412–413), the term “emergence” is used, for the first time, in this new philosophical sense. Lewes opposes it to the term “resultant.” This opposition was drawn in the light of a fundamental distinction, elaborated by Stuart Mill (1843), between two ways in which several causes can act together to produce an effect. There are cases in which the joint effect of the causes is the sum of their separate effects, and cases in which it is different (Mill 1843, 427 ff.). Mill called the laws associated with the first type of causation, “homopathic,” and the laws associated with the second type, “heteropathic.” Heteropathic laws are the emergent laws of the special sciences, such as chemistry, biology, or psychology. According to Mill (1843, 431 ff.), given their particular nature, heteropathic effects cannot be accounted for by the linear principle of composition of causes (so named by analogy with the linear superposition principle of the composition of forces of Classical Mechanics). Therefore, if an entity is generated as an effect of non-additive relations between several other entities, that entity cannot be reduced to the latter in the traditional mechanistic way. That is the reason why Lloyd Morgan and C. D. Broad would later reject the validity of the principle of “algebraic summation” (Morgan 1923, p. 8) or the ideal of “Pure Mechanism” (Broad 1925, pp. 44–52) when it comes to explaining emergent processes. Despite their

differences, the first Emergentists agreed in identifying emergence with the generation of certain high-level organizations, whose properties or laws cannot be predicted, deduced, or explained, even in theory, solely in terms of the properties and laws of their respective lower levels. In other words, it is not possible to predict, deduce, or explain an emergent organization and its defining features from its constituents alone, taken by themselves or apart from their very organization. The first Emergentism thus represents an essentially organizational view directed against the atomistic model of micro-reductionism. According to Alexander (1920, pp. 45–46, 72–73, 323–329), emergent entities are high-level “constellations” of lower-level spatiotemporal motions instantiating qualities and lawful patterns of behavior that cannot be explained by or predicted from the most complete knowledge of their respective lower levels before they are so organized. According to Morgan (1923, pp. 15–16, 19, 64), at any stage of evolution, new kinds of entities, that is, new kinds of non-additive relatedness, manifest new properties and new ways of acting and interacting in the world of which there are no instances at lower or previous levels of organization. The ontological robustness of such emergent organizations is reinforced by the fact that they can affect “the go of events” at lower levels. Morgan’s emergentism explicitly includes the idea of a systemic or downward causation: “how things go” crucially depends on the level of relatedness at which events run their course (Morgan 1923, p. 16, 21, 278, 298). Among the first Emergentists, Broad was the author who developed the most the epistemological dimension of emergence theory. According to Broad, three classes of properties can be instantiated by composite systems. Ordinarily neutral properties are properties equally shared by the systems and their parts (such as mass). Reducible properties are systems’ properties that can, at least in theory, be deduced from structures, properties and laws manifested in lower levels or orders (such as the beating of the heart). Ultimate properties are systems’ properties that cannot be deduced, even in theory, from what we know from the lower orders (such as the reproduction of living organisms),

being thus considered emergents (Broad 1925, pp. 78–79). A property of a system organized in a specific *R*-way is emergent because it cannot, even in theory, be deduced from the most complete knowledge of the behaviors that system’s parts instantiate either in isolation or in any organization different from *R* (Broad 1925, p. 61). Here comes into play the role of what Broad called trans-ordinal laws, that is, laws which state that all systems composed of such and such lower-order parts in such and such proportions and relations have such higher-order properties. According to Broad, systemic properties, systemic intra-ordinal laws and trans-ordinal laws are emergent insofar as they cannot be deduced from laws of lower orders plus some general laws of composition (Broad 1925, pp. 64–65, 77–79). Emergent properties require specific laws of composition for the specific kinds of organizations that instantiate them. And in this sense, emergent properties and laws defy the characteristic micro or lower-level reductionism of classical mechanistic theory (Broad 1925, pp. 64–65, 77–79).

Despite their unquestionable merit in highlighting the limits of the classical mechanistic view, or in their attempt to reconcile the nature, at the same time monist and pluralist, of reality and the continuist and discontinuist views of evolution, it is widely recognized that the first Emergentists’ views also comprised problematic assumptions. Emergence was identified with micro-irreducible organizations. The problem now is to explain how such organizations get to be produced from their respective lower levels. It is not enough to say that emergents must be accepted with “natural piety,” as brute empirical facts admitting no explanation (Alexander 1920, pp. 46–47; Morgan 1923, pp. 1–12). The other problem was the postulation of a “*nisus* towards deity” to explain why nature’s evolution involves the emergence of higher forms of existence (Alexander 1920, pp. 346–347; Morgan 1923, p. 36). Finally, some of the chemical and biological examples of emergence then given, turned out to be discarded as real cases of emergence, at least in the sense of representing in-principle unexplainable facts (McLaughlin 1992). This partially explains why Emergentism would be later

perceived as a somehow skeptic attitude towards science, being largely ignored or criticized in the following decades of the twentieth century. The increasing dominance that Logical positivism and extreme empiricist views had in the philosophy of science after the 1930s also contributed to the temporary demise of emergentism.

The Rebirth of Emergentism

Nevertheless, between the late 1960s and beginning of the 1970s, the emergence-mechanism-reduction debate was gradually resumed. Among the multiple factors explaining this revival, it is worth mentioning the advent of Cybernetics and its associated theories of Information and Complexity in the late 1940s. The role that such theories play in the reassessment of that debate can be hardly overrated. Indeed, not only did they provide some plausible examples of self-organizing emergent processes equally observable in artificial, physicochemical, biological, cognitive, and social systems, but, for that very reason, they succeeded in overcoming the old rigid dichotomies between simple matter, life, and mind, trying to disclose the causal mechanisms through which the generation of such levels of organization and their crucial differences can be explained. More than that, through the use of Cybernetics' new tools and concepts, it was found that self-organizing processes not only are not exclusive to the realm of life but can also be described and explained in causal-mechanical terms. Still, this only became possible because mechanist theory was itself developed beyond the limits of its previous atomist, linear, and micro-reductionist paradigmatic views. Through the study of new types of causal processes, such as feedback and feed-forward cyclic relations, centralized and distributed hierarchical control, self-organization, adaptation, and even teleonomic behavior, Cybernetics paved the way to the development of a sort of neo-mechanism that would eventually lead to the reevaluation of old oppositions, such as emergentism/mechanism, emergence/explanation or explanation/reduction (Atlan 2011; Bechtel and Richardson 2010; Wimsatt 2007). In fact, some of

the most important emergentists approaches put forward between the late 1960s and the 1970s, such as those developed by the neuroscientist Roger Sperry, the social scientist Donald Campbell, or the philosopher of biology William Wimsatt, were precisely carried out in the light of this new theoretical framework. The other important factor explaining the re-emergence of Emergentism comes from within philosophy itself: the increasing recognition of the limits of the neo-positivist nomological model of explanation and its associated theory-reduction model and Unity-of-Science program. At this juncture starts a new chapter in the history of Emergentism. Informed by this new scientific and philosophical background, the problem of the relations between the different levels of organization – including those found within each science – and, in particular, the notion of organizational emergence bequeathed by the first Emergentists, are readdressed. Since levels of organization typically involve part-whole relations, the debate among philosophers evolved around the nature of the relations of dependence and independence between parts and wholes (supervenience, multiple realization, dynamic autonomy, etc.), in terms of their respective sets of properties, laws, and causal powers.

At this point we may then ask: How does Emergentism relate with the possible? How can emergence theory contribute to a theorization of that concept? As the overview presented above shows, the first Emergentists sought to argue that the domain of world's possibilities is not closed. Indeed, in its most general and basic sense, the notion of emergence refers to the generation of unexpected new possibilities (new properties, systems, states of affairs, relations, laws, behaviors, dispositions, capacities, or causal powers) leading to the formation of new, qualitatively different and irreducible levels or domains of existence. Given the particular subject of this Encyclopedia and the vast and multifaceted literature on emergence, the next sections will be limited to surveying some of the contemporary views on emergence that may be considered particularly relevant for the theorization of the possible from an ontological perspective.

Emergence Theory and the Possible

From the point of view of part-whole relations, emergence can be defined as the proper opposite of aggregativity. According to Wimsatt (2007, pp. 274–281), a system's property is completely aggregative – and thus not emergent – if the following four conditions are jointly satisfied: (i) the system property is invariant under operations rearranging the parts in the system or interchanging any number of parts with a corresponding number of parts from a relevant equivalence class of parts; (ii) the system property preserves its qualitative similarity under addition or subtraction of parts; (iii) the system property is invariant under operations involving decomposition and reaggregation of parts; and (iv) the system property is not affected by any cooperative or inhibitory interactions among the system's parts. Emergence thus comes in degrees. The failure of the first three conditions corresponds to an essentially combinatorial notion of organizational emergence. A system is emergent from the set of its parts, because some of its defining properties, powers, and eventually laws, are directly grounded on a specific global or macro-organization of its parts. Hence, the system can be taken as the real instantiator of some of its properties (*viz.*, its organizational properties) and, thus, as the real causal agent regarding the causal powers associated with such properties. Still, the parts are qualitatively unaffected by their integration in that organization, thereby instantiating the same properties and powers which they manifest, or would manifest, in any other kind of structure or even in an idealized state of complete isolation. This corresponds, in sum, to the idea that the emergence of a system's property relative to the properties of its parts indicates its dependence on their mode of organization. The violation of the fourth condition means that the system's property is dependent on the context sensitivity of the relational parts' properties to intra-systemic conditions. In this case, systemic emergence involves not only a dependence on a particular mode of organization of the parts but also on a certain organizational interdependence between the parts themselves (Wimsatt 2007, pp. 275–277). The idea that emergence

necessarily involves some kind of change or transformation of the base or lower-level entities has been variously stressed by many authors. The disagreement concerns the nature and degree of that change.

According to one view, presented by Wilson (2021) as the weak form of emergence, there is emergence when the parts of a system activate some of their “micro-latent powers” by virtue of their very organization (Shoemaker 2002). The powers associated with an emergent system's property thus constitute a proper subset of the lower-level powers of the parts. The system just inherits some of the powers of its parts. Emergent properties are then just actualizations of powers already existing in potency. For this reason, emergent powers are new but only in their state of actuality. Emergentism gets here close to a potentialist preformationism. A stronger notion of interlevel emergence defends that emergence necessarily involves a qualitative change of lower-level entities by virtue of their integration, as parts, in certain systems, but that the emergent properties and powers are genuinely high-level features of the global organizations of those systems. According to one of such views, emergent powers are real powers of certain wholes, but their parts only change by actualizing some of their already possessed intrinsic powers (O'Connor and Wong 2005). According to another view, parts can also acquire genuinely new causal powers (Gillett 2016; Santos 2015, 2020; Silberstein 2017). Against the “simple” view of aggregation, Gillett (2016, pp. 17–18) advocates the “conditioned” view of aggregation, which implies that parts may have some “differential” powers in complex collectives that they would not have if the laws or principles applying in simpler collectives exhaustively applied in the complex aggregation. In Santos (2015, 2020)' view, entities can acquire genuinely new properties and powers as interacting parts of certain structures of transformative relations. These relations are the key mechanism for the formation of genuinely new emergent properties and powers at the higher level of their systems' organizations. When embedded in specific structures of transformative relations, parts are qualitatively modified, and their behaviors conditioned in a system-wide interdependent

way. This means that lower levels are themselves partially determined by their integration in certain higher-level structures, thereby contradicting the individualistic essentialism of atomistic metaphysics and its associated lower-level reductionism. The problem here is whether the way systems affect their parts can be conceived in literal causal terms, although this issue is strongly biased by the widespread reduction of the notion of causation to physical processes of energy transference. For example, Gillett (2016) argues that certain composed entities determine (in a so-called “machretic” way) some of the powers of their components in a non-causal and non-compositional way. One way or another, particularly in hierarchically organized systems structured by feedback causal loops, system-wide constraints seem to have the power to not only constrain (by restricting) but also enable (by empowering) their constituent parts in terms of the causal powers and actual activities they may exhibit. In short, certain systems have the downward determinative power of restricting some possibilities while enabling others (Bishop and Silberstein 2019; Santos 2020). A similar view can be found, in contemporary social theory, in the notion of structural conditioning elaborated by Archer (1995). This notion contrasts with the atomistic view disseminated in the social sciences through methodological individualism and conveyed by the employment of agent-based models, rational choice theory, and decision and game theoretic principles (Humphreys 2016, pp. 1–15; Auyang 1999: 51–54; 120–121; 208–210). According to Archer’s morphogenetic approach, by engaging in interactions producing some change in the macrostructure of their system, the parts are also changed. There is thus a process of “double morphogenesis.” Furthermore, according to Archer, it is crucial to examine the interplay between the social structures and the human agency in order to explain society as a whole. Structure and agency operate over different time periods and their interplay can be investigated on the basis of two fundamental propositions: (i) that structure necessarily pre-dates the action (s) leading to its reproduction or transformation; and (ii) that structural elaboration necessarily post-dates the action sequences that give rise to

it (Archer 1995, p. 15, 76, 168). All these views thus entail the idea that there is a reciprocal and partial codetermination between systems and their parts, rather than an exclusively unidirectional relation of micro-determination. According to Gillett (2016), scientific emergentism calls for a “mutualist” position in the sense that one must recognize the existence of many levels of mutually determinative, and interdependent, composed entities. According to Silberstein’s notion of contextual emergence, the arrow of determination and explanation must always be multidirectional rather than exclusively bottom-up (Silberstein 2017, pp. 167–168). Santos (2020) argued that there is an in-principle compatibility between a relational-transformational notion of emergence and an interlevel integrative neo-mechanistic model of explanation, providing as an example, the formation process of the structural and functional identity of eukaryotic cells. One way or another, thus conceived, interlevel emergence only opposes to micro-reductionism, not to explanation.

Finally, two other perspectives put forward the alternative idea that emergence can be viewed no longer as a process leading from one compositional level of organization to another, but rather as a process occurring at a same, single level. According to a first “single level” perspective (proposed by Ganeri 2011), emergence is not the process whereby certain wholes come to acquire new powers that their parts do not have, but rather a process in which parts are transformed, thereby acquiring new causal powers by virtue of being parts of such wholes (Ganeri 2011, pp. 686–687). Emergence takes place at the level of the parts themselves, and the causal powers that a whole may possess are the new emergent powers that its parts come to acquire in their blending state. For example, it is not the case that a living body, taken as a whole, acquires cognitive powers by virtue of some transformations undergone by its constitutive elements, but rather that the constitutive elements themselves acquire cognitive powers when in the frame of a living body (Ganeri 2011, p. 688). Still, this view allows a kind of downward causation – called “assistive” – in the sense that the macro-states of the system contribute to the later transformations of the system’s constituents

(Ganeri 2011, p. 691). According to a more recent “single level” perspective, emergence does not even involve a relation between different levels of organization. Emergence simply relates different domains of properties and laws instantiated at different times. As a consequence, levels-talk can be discarded as irrelevant. This so-called “flat” account of emergence (Sartenaer 2018) has its roots in Humphreys (1997)’ notion of fusion emergence, which takes place when two or more elements, or their properties, fuse together in such a way that their individual existence is lost in forming a new single unified whole. Quantum entangled states or the production of molecules by covalent bonding are given as paradigmatic examples. According to Humphreys (2016) new account of transformational emergence – presented as a generalization of his earlier “fusion” approach – emergence occurs when an individual that is considered to be a fundamental element of a particular nomological domain transforms, by a change in at least one of its essential properties, into a different kind of individual, thereby becoming a member of a different nomological domain (Humphreys 2016, p. 60). The transformation of a muon into an electron, electron neutrino, or muon neutrino is given as a prototypical example. Guay and Sartenaer (2016) presented the example of the fractional quantum Hall effect – a process whereby from a gas of electrons, classified as fermions, are produced anyons, which are called quasi-particles, since they are neither bosons nor fermions. One distinctive feature of this approach is that emergence has nothing to do with modes of relatedness or organization, as transformation processes of flat emergence do not necessarily involve relations or interactions to produce or explain them (Sartenaer 2018, p. 9).

Forms of Predeterminism and Their Alternatives

From an ontological point of view, there is no doubt that interlevel or part-whole emergence stands in opposition to any form of synchronic micro-determinism or micro-reduction (either in structural or functionalist terms). But what about

diachronic determinism or micro-predeterminism? Is the domain of possibilities somehow fixed *ab initio*? Are all system’s properties or powers inherited from potentialities which their parts already-always bring with them? This is a contentious issue. For example, Alexander (1920, p. 323) and Broad (1925, p. 491) did not see any incompatibility between free mental action or genuine novelty and complete determinism. On the contrary, Morgan (1923, pp. 138–139) conceived emergence as an epigenetic, rather than a preformationist, process. In contemporary theories of emergence, we find other divergences. From a diachronic interlevel perspective, micro-determinism may mean that the system’s parts predetermine in a necessitarian way (in a program-like fashion) all properties or powers that their system will instantiate in the future. In a weaker sense, it may mean that the parts already have in themselves, as intrinsic potentialities (in a preformationist fashion), all properties or powers that their system may or may not instantiate in the future. In its diachronic version, predeterminism can thus assume an actualist or potentialist form. Against both perspectives, one may argue for a relational-constructionist view of potentialism, according to which relations may not only activate the manifestation of already existing potentialities but also construe new ones (Santos 2015, 2020). According to Sartenaer (2018), the “flat” approach to transformational emergence is, by definition, opposed to preformationism, defined as the view according to which the causal powers of what is (causally or otherwise) determined by x already exist in what is the determinative source of x , either in a manifest or in a latent way. On the contrary, argues Sartenaer (2018, p. 18), the “subset view” of emergence is clearly preformationist, while O’Connor and Wong (2005)’s view is only committed to a preformationism about causation, according to which the causal powers of an effect already exist in its cause, either in a manifest or in a latent way. As this brief overview shows, it is not only clear the intimate relationship between Emergentism and the notion of the possible, but also the different theorizations of the possible that can be sustained and developed within an emergentist perspective.

Griffone, Sasso Marconi, Italy

Abstract

Emotion is here conceptualized as action disposition, in the sense that the primary function of human emotion is to motivate action. Creative behavior, among others, provides a concrete action bringing new insights into the possible and its cultivation. The role of emotion in creativity has been of considerable interest, with different authors depicting emotion as an intermediary state between a series of situational and personality predictors, on the one hand, and creative performance, on the other. Emotion is here explored in the

context of creativity research in order to understand how motivational tendencies can help in understanding the possibility of creative actions that take place “in between” actors and their environment. This entry then starts with a brief conceptualization of emotion as action disposition before moving to the relationship between emotion and creativity. This relation will be then examined taking into consideration the notion of the possible within an action framework. Some final considerations are offered toward the end to reflect on the importance of studying emotion, conceptualized as action disposition, in creativity, which provides a concrete investigation of the possible.

Emotion as Action Disposition

A number of authors have attempted to elucidate the origin, neurophysiology, experience, and function of emotions, proposing different theories about emotion. Part of the difficulty in studying emotion is defining it. Indeed, although we have a huge terminology for describing our individual emotions, it is difficult to find consistency between researchers about a single shared definition of emotion. For instance, some investigators have highlighted the discrete nature of emotions, along with the specificity of physiological responses associated with each emotion, such as anger, disgust, fear, happiness, sadness, and surprise (Ekman et al. 1983). Differently, other scientists have stressed the key role of cognitive processing such as appraisal in defining the expression and experience of emotion (Schachter 1975; Schachter and Singer 1962; Scherer 1987, 2001). Lastly, other researchers have emphasized the role of motivation in regulating and controlling behavioral and physiological reactions in both human and animals (Lang et al. 1997; Lang and Davis 2006; Russell and Barrett 1999). Despite the lack of a definite characterization of

emotion, one point that many researchers agree is that the main function of emotion is to motivate *action*. Actually, the term “emotion” stems from the Latin *movere*, which means “something that moves one.” Whereas “emotion” is usually used for describing events that are experienced to be moving, generating an affective response in individuals, “motivation” is typically used in reading the actions of animals. It is worthy of notice that individuals and animals share some important characteristics, i.e., the responses that happen when an organism perceives and responds to significant events in the course of surviving. From an evolutionary perspective, emotions are expressed through actions directed to preserve survival (Darwin 1872).

The literature is characterized by a rich set of observations concerning the relation between emotion and action in both human and nonhuman primates. For example, anatomical studies in monkeys have demonstrated the existence of influences of the limbic system, a set of brain structures supporting a variety of functions including emotion and motivation, on motor system. Specifically, some components of the limbic system and the anterior cingulate areas seem to be connected to the supplementary motor area, which in turn is linked with motor cingulate areas (Luppino et al. 1993; Morecraft and van Hoesen 1992). Similar evidences have been found in humans, in which the translation of emotion to action seems to involve the nucleus accumbens that receives inputs from limbic structures, by direct and indirect mesolimbic dopaminergic projections from the ventral tegmental area of Tsai, and sends signals to the motor system via the globus pallidus (Mogenson et al. 1980). Recent human neuroimaging studies seem to corroborate that emotional information processing produces higher activity of emotion-related areas together with action preparation-related areas (De Gelder et al. 2004; Grèzes et al. 2007).

Although emotional expression is extremely varied, emotions can be described as a result of evolution as the motivation to avoid threats and attain appetitive goals endorsed our ancestors to survive and eventually develop into what our species is today. This perspective defines that

emotions are founded on the activation of motivational circuits that are engaged by significant stimuli that symbolize threats or supports to the organism's survival. In other words, action is a basic constituent of goal-directed behaviors, such as attack, flight, food procurement, and other motivational-emotional states. Using the terminology of Konorski (1967), the "emotive brain" (i.e., the limbic system) contributes to the initiation of biologically significant actions. In other words, in both individuals and animals, stimuli that support survival produce behaviors toward the eliciting stimulus, whereas those that menace the organism engage retraction, escape, or avoidance. Undoubtedly, this simplistic approach involving a bidirectional goal-related behavior cannot contain the many subgoals of individuals, who are more creative and flexible in order to interact with the complex environment in which we find ourselves. However, studies from affective language confirmed the view that different emotions might be organized into easier bidirectional actions of approach and withdrawal. For instance, Wundt in his approach about the introspection described that pleasure, tension, and inhibition were the three primary dimensions of feelings (Wundt 1896). Similarly, Titchener (1908) emphasized the principal dimensions of pleasantness and unpleasantness. Some other researchers later assessed this inquiry empirically, by using evaluative responses of individuals to a series of stimuli. Specifically, Russell and Barrett (1999) proposed a two-dimensional structure for describing the affective domain: the valence (pleasant vs. unpleasant) and activation (calm vs. aroused) dimensions (see also Barrett 2006; Russell 2003). Following a similar motivational approach, Konorski (1967) suggested that emotional states are consistent with a preservative/protective organization: preservative emotions involve affects as sexual passion, joy, and nurturance, whereas protective affects embrace fear and anger. More recently, Rolls (2004) suggested that emotions can be defined as states elicited by rewards and punishers, which functions include working to obtain or avoid the rewards and punishers, respectively. A reward is anything for which an individual (or an animal) will work (e.g.,

winning a wide sum of money). A punisher is anything that an individual (or an animal) will escape from or avoid (e.g., approaching car). Based on the similarities between individuals and animals, Lang et al. (1997) offered one of the most influential theoretical model on human emotion, defining it as the result of a dynamic influence of language, physiological, and behavioral responses. Specifically, Lang proposed that human emotions can be measured as (i) expressive and evaluative language of affective experience that involves reports about awareness of affective reactions such as verbal descriptions (e.g., "I'm sad"), ratings of emotion (e.g., ratings of sad on 1 to 10-point scale), or reports of physiological responses (e.g., identification of bodily changes); (ii) physiological changes that involve bodily actions mediated by somatic and autonomic systems; and (iii) behavioral responses, which are usually measured in studies of motivated behavior in the animal laboratory, such as propensity of avoidance. Definitely, significant stimuli engage neural systems that enhance attention and facilitate perceptual processing and active a series of reflex responses that mobilize the organism for the motor action (Hebb 1949; Schneirla 1959; see also Lang and Davis 2006). Thus, overall, human emotion can be described as disposition to action (Frijda 1986; Lang 1979, 1985), to identify environmental events that menace or sustain our life.

Emotion in Creativity Research

Among others, creative behavior provides a concrete action bringing new insights into the possible and its cultivation. Focusing on the role of emotion in creativity research allows introducing the notion of human possibility in the sense of both becoming conscious of it and dynamically exploring it. For this reason, emotion is here analyzed in the context of creative behavior, to understand how motivational tendencies can help in understanding the possibility of creative actions that take place "in between" actors and their environment. Creative actions are in fact conceived as the basis of the possible in all its forms of

expression including possible worlds, possible selves, possible pasts, and possible futures (Glăveanu 2018). Being creative enables to examine a problem, situation, or concern from multiple viewpoints, exploiting and expanding the possible for both self and others in the environment. In other words, creativity is here employed in trying to answer the question “what is possible?”.

For survival and prosperity, people need to adapt to changing environments, to solve problems, generate new ideas and insights, and create new products and services. Human brains have evolved to sustain and promote the creative behavior. The process of creative thinking is widely defined as the ability to generate outcomes potentially original and effective for a particular context (Eysenck 1993; Beghetto and Kaufman 2007; Corazza 2016; Runco 2004; Simonton 2003; Sternberg and Lubart 1999). Within the human creative cognition, emotion stands out as one of the most broadly studied and least disputed predictors of creativity, as everyday emotions can operate as strong intrinsic and/or extrinsic energies able to impact the creative thinking process (Amabile 1983; Amabile et al. 2005; Davis 2009; Zenasni and Lubart 2002). They are basically proposed as mediators and moderators of the creative thinking process. Only lately some exciting research has clarified the role played by emotions, measured in terms of hedonic valence and affective arousal, on creative performance (Baas et al. 2008; De Dreu et al. 2008; Silvia and Brown 2007), by placing the emotional experience as one of the key mechanism underlying the creative process.

A number of studies have employed a broad range of induction procedures (e.g., emotional imagery, affective stimuli, etc.) to engage participants in the intended emotional states, measuring various indexes of creativity. The results from the majority of these studies reveal that positive affective states, as compared to neutral conditions, enhance creative performance focusing on specific phases of divergent thinking (i.e., generation, evaluation), categorization (i.e., cognitive flexibility), remote associate test, and insight problem-solving tasks, as individuals tend to

make richer associations between knowledge frames when in a positive affective state than when in a neutral state (Ashby et al. 1999; Lyubomirsky et al. 2005; Mastria et al. 2019). Other studies suggested that it is the intensity of the emotional experience measured with both positive and negative high-arousal emotional states than can enable creativity, as compared to low-arousal states (George and Zhou 2007; Russ and Grossman McKee 1990). In line with these findings, it has been shown that highly arousing circumstances (including negative ones such as frustration) can even booster creative performance in individuals with specific personality traits (Agnoli et al. 2019). As a whole, although it is not still completely clear the extent to which positive and negative states facilitate or inhibit creativity, scientists are largely in agreement that emotions affect various indexes of creativity.

In the attempt to understand the emotion-creativity link, neuroscience has pointed to the contribution of the dopaminergic (DA) system in creativity (Heilman et al. 2003; Flaherty 2005). Individual differences in terms of creative performance, measured by divergent thinking tasks, in which individuals are required to generate ideas by exploring many possible solutions in response to verbal or figural stimuli, were found to be positively correlated with gray matter in DA system regions (Takeuchi et al. 2010). Moreover, cortical dopaminergic activity seems to be involved in cognitive flexibility (Cools 2008; Garcia-Garcia et al. 2010), which is a key executive function that facilitates the creation of original and effective ideas in creativity. Some interesting research has pointed out that phasic changes in dopamine levels, affective changes, and changes in creative performance are strongly interrelated. Indeed, the neurotransmitter dopamine seems to mediate the relationship between human creative performance and emotion, such that participants with medium eye blink rates (EBR), which is an indirect but well-established physiological marker of individual dopamine levels (Groman et al. 2014), showed more flexible behavior in divergent thinking (DT) tasks (Chermahini and Hommel 2010). In addition, positive emotions, presumably

associated with increased dopamine release in the brain (Beninger 1991; Schultz 1992), enhanced EBR, predicting the associated increase of flexibility in DT (Chermahini and Hommel 2012). As a whole, an adequate level of dopaminergic activation seems to enhance creativity in tasks focusing in particular on divergent thinking, and DA system mediates the connection between positive emotion and creativity.

The positive impact of emotion on creativity depending on DA system calls for closer consideration of individual differences in terms of personality. Among the personality traits, trait emotional intelligence (i.e., trait EI) is the individual tendency to process emotional information, including recognition of one's own emotions and emotions of other persons, and adaptive regulation of emotions, which eventually requires a more effective solution of life difficulties (Petrides 2009). In particular, it has demonstrated a strong relationship between trait EI and affective arousal, showing that trait EI can modulate the impact of arousal on behavior (Pittarello et al. 2018). In particular, individuals with high EI are able to exploit emotionally arousing experiences, especially the negative ones associated to creative frustration, to increase their creative performance (Agnoli et al. 2019). Finally and importantly, indicators of emotional intelligence have been linked with the activity in the DA system, as the gene of dopamine receptor DRD2 takes an active part in providing emotional recognition, emotional stability, and physiology of the brain during perception of affective stimuli (Kosonogov et al. 2019). Overall, empirical research on the relationship between creativity and emotion, measured from a subjective, behavioral, and physiological point of view, seems to provide a direct evidence for a strong interrelationship between these two complex phenomena.

Emotion, Creativity, and the Possible

A strong interrelationship seems to emerge between emotion and creativity, both conceived within an action framework. Emotion exactly means to move, touch, or prepare for action, and

this is strictly associated with actions of approach and withdrawal characterizing the basic behavioral responses supporting survival (Frijda 1986; Lang et al. 1997). In a similar manner, creativity can be conceptualized as action, since a creative behavior starts from an understanding of the interactions between creators and their environment (Glăveanu et al. 2013). Thus, emotion was addressed here in the context of creativity research, as creative actions can offer a unique perspective to the topic of the possible, through specific experiences such as remembering the past, imaging the future, considering alternatives, anticipating problems, and engaging counterfactual thinking. A creative act emerges as a relational, intersubjective phenomenon incorporating an organism in its environment and opening new possibilities for the person, the group, or society as a whole, integrating emotional and motivational aspects (Glăveanu 2018). Emotion in such creative context may modulate or “rules” the creative actions. Emotion or motivational tendencies have in fact been considered as an integral part of the process of creation. Emotional experience modulates the creative thinking process at the beginning, during, and at the end of the activity. It is enough to consider the excitement or motivation that drives the generation of a creative idea or the variety of emotions while working on it or the sense of pleasure and satisfaction (or desperation) once reached (or unreached) a truly creative idea (i.e., creative inconclusiveness). Emotions have been recently described as the core or the “spinal cord” of the creative thinking process, as emotional experience is the essential (although not enough) determinant of the process (Agnoli and Corazza 2019). In fact, embracing the idea that motivational forces drive the thinker's creative behavior, this would help us to understand the complex interconnection between creativity and emotion, examined from different perspectives (subjective, physiological, and behavioral). This means that emotion might not only influence the process of creation, as it has been suggested in the past, but lead to its realization. Put differently, emotions in both human and animal life are the organizers of the creative interactions with the world. Such interactions are constructed and

reconstructed within explorations of the past, the future, and the possible. Driven by this new perspective that takes into consideration the concept of the possible, future research could disentangle how and the extent to which emotional and/or motivational tendencies determine the creative thinker's actions.

Conclusion

Emotion actually takes place at and through the face between individual and the environment. Similarly, creative actions occur not “inside” creators but “in between” creators and their environment, offering a unique perspective to the topic of the possible. The research on emotion-creativity link seems to show that emotions could be conceived as “supporters” of the creative behavior, in the sense that the dynamic interplay between “internal” and “external” creative actions may be driven by motivational tendencies. From this reasoning, it becomes clear that emotion and motivation play a crucial role in defining the creative thinking process. Here, it is argued that a deeper understanding of the interplay between emotion and creativity needs to be guided by an integrative framework that incorporates the notion of action, including a relationship to the future and the possible. Finally, it is important to highlight that, given the difficulty in defining human emotion and in explaining the interconnection between emotion and creativity, this reasoning is not intended to provide a comprehensive explanation of these complex dynamics, but it is meant to provide a first reflection on the utility of considering an action framework for the study of emotion in creativity, possibly providing a more concrete investigation of the possible.

Emotional Intelligence

Sergio Agnoli

Marconi Institute for Creativity, University of Bologna, Sasso Marconi, Italy

Abstract

Emotional intelligence (EI) is here analyzed as a construct referring to the individual differences in perceiving, regulating, managing, and exploiting emotions, assuming in particular a trait approach to the exploration of the phenomenon. Specifically, the role of trait EI in the definition of the possible in space and in time is addressed, analyzing how individual differences in the management and use of emotions can explain the emerging of different pasts, different futures, as well as different possible worlds. Moreover, the role of trait EI in the expression of the individual potential is explored, taking as example two research topics (i.e., prosocial behavior and creative performance) to understand how emotional intelligence can help in understanding the emerging of possible selves. Finally, future possible research scenarios are offered to explore the use of trait EI as a study variable in the investigation of the possible.

Keywords

Emotional intelligence · Emotional self-efficacy · Trait EI · Individual differences · Emotion management · Emotion regulation · Potential

Introduction: Emotional Intelligence as the Realm of Subjective Adaptation

Emotional intelligence is a psychological construct that is entered in people's common sense, and it is commonly used to identify the most adapt way to exploit emotions in several life contexts, from work to everyday life. In a way akin to intelligence, which makes reference to the most adapt cognitive abilities to answer to the world

complexity (see the ► “Intelligence” entry in this encyclopedia), the emotional intelligence concept is indeed usually intended as the best use of emotions to adapt to the complexity of the environment. The term was first coined by Salovey and Mayer (1990), who referred to emotional intelligence as a multicomponent construct defined by a set of emotional abilities used to effectively appraise, express, and regulate emotions in oneself and others and to exploit emotions to plan and achieve in one’s life. The term has been then spread across the wide audience through the best seller *Emotional Intelligence* by Goleman (1995), who extracted principles from the emotional intelligence research to apply this concept to several everyday domains. Emotional intelligence research then extensively demonstrated the theoretical and practical implications of a construct (which is distinct from the cognitive intelligence construct) that conveys the ways in which people express, regulate, and manage emotions in oneself and others. Several studies and meta-analytical research demonstrated the predictive and explicative power of emotional intelligence on a variety of variables, ranging to psychological (Andrei et al. 2014, 2016) and physical well-being (Andrei et al. 2018; Andrei and Petrides 2013) to scholastic (e.g., Agnoli et al. 2012) or work success (Brackett et al. 2011).

Theoretically speaking, one of the central questions in the study of emotional intelligence pertains whether this construct can be intended in a similar way to cognitive intelligence, which is identified as “the set of abilities involved in the achievement of rationally chosen goals” (Sternberg 1990, p. 43) and measured through maximum performance tests. According to Thorndike (1921), this set of abilities can be considered as “good responses from the point of view of truths or facts.” An objective definition of the truth as well as of the correctness of the responses is implicit into these definitions of intelligence. This same approach has been adopted to explore and define emotional intelligence according to the ability approach (Mayer et al. 2008), which identifies several emotional skills organized around four distinct emotional abilities: perceiving emotions, using emotions, understanding emotions,

and managing emotions. This approach conceives these abilities as essential to adapt correctly to the world; all behaviors provided using each of these abilities can be judged with respect to the degree of their correctness, which is determined through the correspondence with the same behaviors provided by a series of experts or by the general population. The need of a “correct truth” has been a point of criticism to this approach (for a review, see Fiori and Vesely-Maillefer 2018). In other terms, can the concept of correct or best performance (identified through truly veridical criteria, such as the responses of experts) be associated with the term “emotions,” which is by definition the realm of subjectivity? Does a *correct* emotional response exist? Even if the concept of correct can be defined as the most adapt emotional behavior in a given context, as identified by consensus in a specific group of experts, culture, or society, this approach opens the door to a variability in the definition of the concept of *correct*, which does not exist, for instance, in the domain of cognitive intelligence. This is the main reason why the trait approach to emotional intelligence proposed by Petrides (which is defined as trait emotional intelligence, trait EI; Petrides et al. 2007) includes in the conceptualization of the construct the intimate subjectivity of the phenomenon. Whereas the ability EI approach captures the construct using maximum performance measures, the trait EI approach is focused on the use of self-report instruments (Petrides et al. 2016a). A number of studies have demonstrated the absolute independence of the constructs measured by the two approaches (see Petrides et al. 2016b).

However, the distinction between the ability and the trait approach goes beyond the mere measurement question. It is related to the way the subjective dimension of emotions can be included in the construct of emotional intelligence. According to the trait EI approach, emotional intelligence is located at the lower level of personality hierarchies, and it is constituted by a constellation of emotional perceptions (hence “trait emotional self-efficacy” as an alternative label for the construct; Petrides et al. 2007). In other terms, trait EI conveys all emotional aspects of personality, which is a huge domain complying

with motives, attitudes, social values, interests, emotional tendencies. A series of factorial analyses (Petrides et al. 2016a; van der Linden et al. 2017, 2018) showed that all these emotional aspects can be organized around 15 different facets which form 4 broad factors (well-being, self-control, emotionality, sociability). According to the trait EI approach, it is the personal aspects of one's emotional perceptions, experiences, and interactions that is central for the definition of emotional intelligence. This approach is therefore particularly suitable to capture the individual differences in the management and use of emotions. In the present entry, the main focus will be to understand how the intimate differences between individuals (i.e., subjectivity) in terms of emotional intelligence are related to the concept of the possible. For this reason, the trait EI approach will be mainly exploited, in order to understand how the perception in emotional self-efficacy can provide new explicative models to the realm of the possible. Through this analysis, specific proposals will be indicated on how the joint exploration of emotional intelligence and the possible can provide new advancements in the understanding of both phenomena.

Emotional Intelligence and the Possible

In order to explore the relationship between emotional intelligence and the possible, it may be of undoubtable convenience to make reference to a framework offering a clear overview of the different declinations of the possible. For this reason, in the following paragraphs, the different ways of engaging with the possible as described by Glăveanu (2018) will be taken into account. Specifically, Glăveanu stated that the possible can be engaged through different perspectives, exploring possible worlds, possible selves, possible futures, and possible pasts. Exploring possible worlds pertains the understanding of the possibility of imagining and creating alternative worlds, both possible inner worlds and possible outside "real" worlds. Possible selves are related to the not-pre-determined nature of human beings. The possibility to conceive possible selves is granted by the

plastic nature of human personality and by its material (i.e., biological), social, and symbolic composition. This level of possible can be identified as the layer where individual differences are ontologically and phenomenologically expressed and conceived. Possible futures are instead related to the possibility to anticipate the direction and expression of reality in different alternative potential futures. Approaching possibility by looking to alternative futures is related to our ability to forecast and to foresight alternative directions for our lives and acting into the reality to realize these possible alternative scenarios. While we live constantly oriented toward the future, we are guided in the present by our identity, which is substantially grounded in the past. When thinking to the past, it is hard to conceive alternative versions of past facts, because of the intrinsically objective nature we assigned to the past. However, the ability to conceive alternative pasts gives us the possibility to create alternative narratives about our identity, to develop structural memories on which to shape our personality, in other terms, to create our identity as persons, communities, cultures, and societies.

If we intend emotional intelligence as the construct that captures the differences between individuals in expressing, regulating, and managing their emotional experiences, it might result particularly significant to understand its relationship with the definition of possible worlds, possible selves, possible futures, and possible pasts. Emotions are indeed our modality to interact with the external and internal world. The modalities through which we express, regulate, and manage the relationships with the environment/context may define our personal self, our possible world, past and future, creating a plethora of alternatives, which are potentially as numerous as the number of people on the world, in the present, in the past, and in the future. In the following paragraphs, the relationships of emotional intelligence with the possible will be discussed, first addressing how trait EI can be associated with the possible in the space (possible worlds) and time (possible pasts and possible futures) and then with the possible definition of potential selves.

Emotional Intelligence and Possible Spaces and Times

Trait EI in possible spaces. The first layer where emotional intelligence can be proposed to define the possible is the space dimension. For space dimension, we do not intend only the physical world, but (especially) the sociocultural space where we are immersed in. This dimension pertains our inner world as well as our external world, both sharing the same sociocultural perspective. These two worlds are a continuous spring of emotional stimuli, which we need to perceive, understand, regulate, and manage. The role of emotional intelligence emerges therefore to be essential in our relationship with the world. However, we are all but passive receivers of the stimuli coming from the inside and from the outside. We are active builders of the worlds by filtering and regulating the emotions and by using the emotional charge coming from the internal and the external world in order to define ourselves and the world itself. A lot could be said on the relationship between trait EI and the social world, taking into account that one of the main dimensions defining this construct is the *sociability* factor. In the following, some implications and reflections inspired by recent research are described.

One of the main functions of emotional intelligence is, according to O'Connor et al. (2017), to optimize (or enhance) our behavioral performance in stressful conditions by regulating negative emotions. This function should not however be associated only to negative or stressful conditions, but to any sort of emotional situations we can encounter in our world. Generally speaking, high trait EI people are more able to increase their performance through the perception, regulation, and management of their emotional reactions. The question hence is what we intend for better performance. In general, a better performance can be defined as the choice/decision or as the behavior that maximizes the advantages to an individual, in other terms, the behavior that allows the individual to adapt in the most suitable way to her/his definition of the world. In order to take the maximum advantages for themselves, high trait EI

individuals exploit at their best the emotions coming from the external worlds. In doing so, they shape their world. Taking about the possible, individual differences in emotional intelligence allow possible alternative worlds to exist between individuals.

Research indeed suggests that different possible worlds are perceived by high trait EI individuals and by low trait EI individuals. First, reality can find its expression in a spectrum of possible alternatives because of the different perception of the emotional stimuli coming from the world. A recent result from the literature on trait EI shows, for instance, that high trait EI individuals have an attentional bias toward positive emotions (Lea et al. 2019). In the study by Lea et al. (2019), high trait EI participants were associated with a higher attention (as measured through eye-tracking) to positive emotional stimuli (happy faces, positive social situations) in comparison with negative or neutral stimuli. Acting on the attentional filters, emotional intelligence is therefore able to shape the perception of the external worlds and the understanding of our social environment, by choosing to pay attention toward positive emotional situation, and to avoid paying attention to negative emotions. A fundamental facet defining trait EI is indeed optimism (Petrides 2009), which is a behavioral tendency to act on the world in a positive modality. This aptitude is able to define (or not define) possible scenarios, which, in the case of high trait EI individuals, lead them to act on the world in a more proactive or positive way.

Can therefore trait EI help explain the possible perspectives we had about our societal environment? Recent results exploring the perception of social harmful events, such as terrorism attacks, seem suggesting that trait EI has a fundamental role in understanding the possible reactions to these events and as a consequence in defining the sociopolitical positioning toward these events. Specifically, in their seminal work, Rubaltelli and colleagues (2020) showed that being exposed to a repeated media coverage of terrorist attacks, being stressful events, can increase our arousal response and as a consequence can alter the perception (in a negative way) of Arab immigrants being the principal perpetrators of these events as represented in

the media. However, this research showed that the trait EI level acts as a main variable in this relationship, being able to regulate the effect of the exposition to terrorist attacks, reducing the arousability of these events. As a main consequence, high trait EI individuals felt less threatened by terrorism and had a better perception of outgroups identified as principal perpetrators of terrorism actions. This example shows how trait EI is able to shape the definition of our social space, and thus the possible in society, through the management of the emotional impact of relevant social events.

What has been described in this paragraph seems to suggest that trait EI is able to drive a positive attitude toward the internal and external environment, being able to shape our world toward positive values. This however is not totally true. As previously said, trait EI is aimed at providing the maximum advantages and adaptation for an individual, which are often related to positive attitudes toward other people and societal challenges. However, the positive disposition of trait EI should be intended as positive returns for the individual and should be freed from moral values. A recent study on the role of trait EI on dishonesty is a clear example of the adaptive function of this trait (Pittarello et al. 2017). In this research, the balance between benefitting from dishonesty (taking advantages from cheating in a computer game) and keeping a positive self-image has been explored. Pittarello et al. (2017) showed that cheating was associated with physiological arousal (higher skin conductance led to reduced cheating). However, trait EI emerged to be able to regulate this effect by reducing the physiological reaction to cheating. As a consequence, high trait EI participants were more likely to benefit from cheating. The findings emerging from this research highlighted how emotional intelligence is able to license people to act unmorally, by reducing the tension existing between acting upon moral beliefs and serving their self-interest. Again, therefore, trait EI seems to shape our possible relationships with the world and with the norms regulating it (see also the ► “Norms” entry in this encyclopedia).

Trait EI in possible times. While emotional intelligence emerges as essential in the representation of possible worlds, it is equally important to highlight that this trait is fundamental in shaping our identity through the representation of possible pasts and by predicting our behavior in possible future scenarios. It is clear that the majority of the results emerging from the research highlighting the importance of trait EI in shaping our perception of and our relationship with the world can be expressed in the representation of past and future worlds. However, some specific results from the literature seem to suggest that trait EI is directly involved in the representation and perception of past events as well as in the way we act on the world to determine possible future scenarios for ourselves and for the others.

Past events and our memories of them are essential contributors for the development of our identity from an individual, cultural, and social point of view. The perception of the past is one of the fundamental bricks on which our identity is founded. Specific psychological constructs have been highlighted as particularly suitable to explain the mechanisms in the perception and representation of the past. Emotional intelligence seems emerging as an important construct in this sense. The representation of the past is, for instance, essential to distinguish truth from falsity. Emotional intelligence has been specifically associated with a higher ability to detect deception (Stewart et al. 2019). According to Stewart et al. (2019), this ability could be essential in driving social situations and social relationships. Moreover, it could be argued that an increased capacity in deception detection could delineate the definition of our narrative of past events, therefore broadening or restricting the number of possible alternative pasts. The narrative of our past events is indeed organized around a selection of central memories, which are main attractors around which our identity is defined. Trait EI has been demonstrated as important in the selection and in the ability to remember past events (Mikolajczak et al. 2009). Mikolajczak et al. (2009) indeed demonstrated that trait EI (and in particular its self-control facet) is highly related to the memory processes related to past memories. Trait EI in

particular allows memory to adapt and diverge according to the situation: in neutral contexts, high trait EI individuals tended to remember with a higher probability positive events, whereas in stressful contexts they are more prone to remember negative events. Low trait EI individuals instead tended to constantly recall average neural memories independently from the context. As per the stressful contexts, these findings suggest that trait EI allows to confront with aversive situations rather to avoid them, which is essential to cope effectively with these events. On the contrary, having a low trait EI level leads to greater mood deterioration and to a higher cortisol secretion in stressful situations (Mikolajczak et al. 2007). These results are consistent with the research on optimism, showing that optimists pay more attention and remember better negative information as well as show a deeper processing of them (Aspinwall et al. 2001). The ability to rely and to remember past negative events could therefore allow to have more expertise and information in present critical situations and could account for the higher ability by high trait EI individuals (and optimists) to cope with these situations. In other terms, the increased spectrum in the ability to remember possible alternative events of the past as well as in the ability to process past emotional events, which are associated with trait EI, might allow to broaden the spectrum of the possible also in the present and in the future. This assumption seems consistent with the results of a recent study exploring the information processing of past performance in financial markets and its association with the investment behavior tendency (Rubaltelli et al. 2016). The findings of this study showed that high trait EI individuals were more aroused (i.e., had a larger pupil dilation) when looking at past performance of stock funds, especially in the case of positive and negative performance. In turn, this higher arousal led them to invest more money (and therefore to risk more) on a fund irrespective from its past performance. Again, the results of this study seem to confirm that a higher sensitivity and ability to manage past emotional events is not only associated with the definition and remembering of past events but also with the definition of present and future possible behaviors.

It is worth highlighting that if on the one hand a high trait EI level can broaden our behavioral possibilities in the present and in the future, on the other hand a low trait EI level could restrict our vision on possible presents and possible futures. Milojević et al. (2016), for example, demonstrated that juvenile delinquents (with an average age of 16 years) were characterized by a lower trait EI as compared to adolescents from the general population as well as by a lower self-efficacy and by a less optimistic representation of themselves and of their past, present, and future. A restricted pessimistic vision of possible futures could be therefore associated in this case with a reiteration of past negative behaviors. Trait EI could be considered important in freeing the potential to conceive possible alternative scenarios for the future and to allow positive (i.e., adaptive) behavioral tendencies to happen in the future. This claim seems to be consistent with the results by Gallitto and Leth-Steensen (2019) who demonstrated in a longitudinal study that trait EI is an important moderator in the relationship between parental nurturing and the development of prosocial behaviors. The finding of this study in particular showed that the level of trait EI of a sample of preadolescents (age range 10–12) interacted with a positive parenting style in predicting (after 2 years) the probability to show prosocial behaviors. Trait EI emerged therefore to be beneficial in fostering positive future functioning, especially when associated with additional favorable factors such as positive parenting nurturance.

Emotional Intelligence and Possible Selves

Research on emotional intelligence found that high trait EI people are more sensitive to emotional stimuli (Petrides and Furnham 2003) and are more prone to pay attention to arousing (both positive and negative) events; in other terms they feel (both positive and negative) emotions at a higher intensity than low EI people, especially when they are asked to cope with these emotions (Petrides and Furnham 2003). As the previous paragraphs highlighted, it is however the use of

this higher emotional charge that makes the real difference between high and low trait EI individuals.

The use of the emotional charge is intrinsically related to the individual potential or, in other terms, to the possible expression of the self in our behavioral performance. The inclusion, the management, and the use of the energy coming from emotions (i.e., from our relationships with the internal and external world) into our behavior are essential elements for broadening our possibility to express alternative behaviors. Without such an energy, our behavior would be stacked into fixed automatisms. The management and use of this energy could allow us to explore unexplored territories into our spaces and times, by putting in place more risky or energy-demanding behaviors that could lead to more adaptive, positive, and new consequences. In the following paragraph, two examples will be provided on the role of trait EI in the expression of the individual potential, in terms of prosocial behavior and creative behavior.

In a first work (Agnoli et al. 2015), the reasons behind the differences existing in the tendency to help others in need have been studied adopting an emotional intelligence perspective. Specifically, the role of trait EI in the expression of the individual potential in the helping behavior has been explored through the use of an experimental paradigm manipulating the feedback to the prosocial behavior acted by a sample of participants. In particular, participants in a first study were asked to perform a task where they could gain money to help children in need. They have been then randomly assigned to one of two conditions: in a first condition, after each of five blocks of trials, they were informed that they were able to save the children (positive feedback condition); in a second condition, after each block, they were informed that were not able to save the children (negative feedback condition). A rapid deterioration of the mood state emerged in the negative condition, and a substantial difference was found between participants characterized by a high level vs. low level of trait emotional intelligence. Whereas low trait EI participants progressively decreased their performance, high trait EI

participants, after an initial significant decrease of performance in the helping task, progressively increased their helping performance in the following blocks of trials. These results showed that even if high trait EI individuals experience an initial higher impact of the emotional events, they used this emotional charge to increase their performance in order to help others in need. The authors called this effect “Sisyphus effect,” since, like the mythological figure, participants felt an increasing amount of inefficacy for their repeated failures, notwithstanding their efforts. However, high trait EI individuals were able to push forward their potential to help others and increased their performance to obtain a success (save children’s lives).

Similar results, using an equally structured experimental paradigm, have been obtained in another study devoted to the analysis of the creative potential (Agnoli et al. 2019). In this study, participants were asked to produce alternative original uses for some common objects (using a classical task for the study of divergent thinking, the Alternative Uses Task, Guilford 1967). Again, participants were randomly assigned to one of two conditions: in a positive feedback condition, after each of five blocks of trials, participants received a feedback informing them that their responses have been creative; in a negative feedback condition, participants were always informed that their responses have not been creative. Again, fundamental differences emerged in the negative conditions. Both high and low trait EI participants were characterized by an increase of emotional arousal (increase of pupil dilation) with the repeated negative feedback. However, whereas low trait EI participants were characterized by a progressive drop in their creative performance (i.e., a decrease in the originality of their response), high trait EI participants increase progressively their creative performance. These results testify that high trait EI allows to include into the creative process the emotional energy coming from the environment, managing the frustration emerging from repeated failures, and charging the process with an emotional energy that allows to push further the creative efforts.

Taken together, the results emerging from these studies showed that trait EI is not only fundamental to manage the emotional energy coming from our interactions with the world, but it is also essential to exploit this energy by transforming it in a further element defining our potential. The behavioral performance is a clear expression of the possible in the self, and it emerges as the result of a complex ensemble of individual (cognitive, conative) and social factors. Emotions play a substantial role into this ensemble, and their management, through emotional intelligence, can be considered as one of main channels for the expression of possible selves.

Conclusions

After taking into consideration different layers where emotional intelligence may be involved in the definition of the possible, it could be interesting to understand whether a trait EI perspective can be explicitly used as a study approach in the exploration of the possible. A first reflection in the use of this perspective is that trait EI can provide insights in the understanding of the possible, as long as emotional reactions (and individual differences in their expression) are taken into consideration in the study. Differently from other types of individual differences (e.g., in personality traits), research on trait EI indeed constantly showed that this construct can be useful in the understanding of a phenomenon when emotions are an integral part of the variable under study. The manipulation of the emotional reactions in particular seems to emerge as a particularly useful approach to explore how differences in the perception and management of emotions can define alternative performance. Experimentally speaking, it would be, for instance, interesting to understand how the manipulation of emotional phenomena can provide new understanding of possible pasts, possible futures, and possible worlds in relation to individual differences in trait EI. Taking, for example, into consideration possible pasts, it would be curious to manipulate the emotional valence (and arousal) associated to past events in order to understand how the

narrative of the past would change in relation to differences in trait EI. At the same time, it would be interesting to manipulate the emotional meaning of present arrays of information or of the actual behavioral performance and to explore how future performance (through a longitudinal approach) or the imagination of future scenarios would change in relation to the ability to manage these emotional reactions.

The exploration of individual differences in emotional intelligence can therefore open new research avenues in the study of the possible. Even if we are often driven in our daily lives by aggregating forces based on common and shared visions of our time, of our space, and of our identity as members of a group, it may be stated that it is in the small differences between individuals that the possible can flourish. The present entry has offered a vision of how individual differences in the management and use of emotions can define our possible spectrum. A role for future research will be to develop specific experimental paradigms to explore how trait EI is involved in the tightening or in the broadening of this spectrum.

²Child Study Center, Yale University, New Haven, CT, USA

Abstract

Empathy is a possibility skill that is critical for social progress and human interactions. It is a nuanced, multifaceted construct that simultaneously refers to a trait and a state, a response, and a process (Cuff et al. 2016). Although defining empathy represents a research topic per se, a common operationalization refers to it as the capacity to place oneself in another's position and understand or feel what that person is experiencing. After an overview of the historical roots of the empathy construct, this entry highlights (1) the dimensions of empathy, (2) the development of empathy, (3) protective and risks factors of empathy development, (4) the measurement of empathy, and (5) methods of prevention and intervention on empathy, with a focus on how encouraging empathy could represent an avenue of transformative change.

Keywords

Affective and cognitive empathy · Theory of mind · Emotion regulation · Social behavior · Social competences · Assessment and training of empathy

Definition

A unified definition of empathy has not been utilized consistently throughout the psychological literature to date. A range of definitions have been proposed, reflecting fundamental variations in conceptualization and operationalization of the construct. For instance, empathy was defined as “the reactions of one individual to the observed experiences of another” (Davis 1983, p. 113), the “understanding of, and identification with, the thoughts, feelings, and motives of another individual” (Hogan 1969, p. 309), or “the process whereby one person tries to understand accurately the subjectivity of another person, without prejudice” (Wispé 1986, p. 320). In a contemporary review, Cuff, Brown, Taylor, and Howat (2016) identified 43 discrete definitions and outlined themes that contrast these conceptualization most saliently, including the dimensions of empathy, its nature as trait or state, or as an automatic versus controlled process. Accordingly, Cuff and colleagues (2016) propose that:

Empathy is an emotional response (affective), dependent upon the interaction between trait capacities and state influences. Empathic processes are automatically elicited but are also shaped by top-down control processes. The resulting emotion is similar to one's perception (directly experienced or imagined) and understanding (cognitive empathy) of the stimulus emotion, with recognition that the source of the emotion is not one's own. (Cuff et al. 2016, p. 150)

After an overview of the historical roots of the empathy construct, this entry highlights (1) the dimensions of empathy, (2) the development of empathy, (3) protective and risks factors of empathy development, (4) the measurement of empathy, and (5) methods of intervention on empathy, which beyond “treating” an empathy deficit could cultivate the possible by augmenting our understating of the world and each other.

Empathy as a Psychological Construct: Origins and Salient Dimensions

The roots of the term empathy trace back to the ancient Greek *empathia* (“in passion”), but its use in the psychological literature is rather recent.

It initially appears in the early twentieth century (e.g., Lipps 1903; Titchener 1909), upon an adaptation of the German term *Einfühlung* (“*feeling into*”) in the fields of Aesthetics and the Arts and coined by Vischer (1873) – a German Art Historian and Philosopher – describing the perception of the subjective qualities in an object, specifically through the projection of the self onto the object. Despite these early uses of the term, Wispé (1986) notes that until the 1980s, the terms empathy, sympathy, or compassion are used interchangeably in the psychological jargon and they have only progressively differentiated from each other since then. One exception was the Rogerian use of the term empathy that emphasized the need for the therapist to try to “live the attitudes of the other” (Rogers 1951, p. 29). While definitionally still challenging to parse out from sympathy and related constructs, a contemporary review of the term (Cuff et al. 2016) identified eight salient themes relating to the nature of empathy across distinct definitions, according to whether (1) they explicitly refer to a distinction of empathy with other related constructs (e.g., sympathy), (2) the components of empathy referred to (e.g., cognitive or affective), (3) the notion of congruency or (incongruency) of emotions elicited in the observer, (4) the impact of external stimuli (e.g., does emotional state of another needs to be explicitly observed or can it be evoked by mere imagination), (5) the distinction between the self and other’s emotional awareness (much empathy research has overlooked that the individual has to recognize that the perceived emotions are separate from the self), (6) its nature as a trait or as a state (i.e., empathy as trait is viewed as a stable capacity, whereas state empathy is viewed as an ability influenced by situational factors), (7) empathy requires a behavioral response rather than recognition, and (8) empathy is an automatic experience or one that is subject to intentional control.

Despite these numerous facets of the construct of empathy identified by Cuff et al. (2016), one of the most common way to operationalize it focuses essentially on the dimensions of empathy and mainly distinguishes cognitive and affective empathy, also coined “dual system” (e.g.,

Shamay-Tsoory et al. 2009). Cognitive empathy comprises of a variety of cognitive processes, all of which contribute to the ability to understand another’s mental state and/or take another’s perspective (for review and neurological underpinning, see Decety and Jackson 2004), that is, perspective taking (“the ability to construct a working model of the emotional states of others” (Reniers et al. 2011, p. 85). In contrast, affective empathy (or emotional empathy) refers to the capacity of being affected by other’s emotional state (that is, emotion contagion) and respond with appropriate emotions to those states (Shamay-Tsoory et al. 2009).

In a recent operationalization, Heyes (2018) articulates both systems to explain the empathic response (Fig. 1; see also Keefe 1976). In her dual-system model, the first system (affective empathy) operates automatically and unconsciously by a motor and/or somatic activation due to an emotional stimulus. This activation causes behavioral and/or physiological changes leading the person to experience an emotional state close to the one he/she observed. These automatic changes trigger the second system called cognitive empathy, which is more conscious and implies controlled processing, such as mindreading, or cognitive and metacognitive appraisal (e.g., the agent conscientiously conceptualizes himself to be in the same emotional state as the target). This processing allows the person to understand what causes the situation and the emotional state felt by others, and also to modulate a controlled response, by reducing or amplifying it, or by displaying prosocial versus antisocial behavior, that may help/comfort or disturb/upset the other (Fig. 1).

The Development of Empathy: Models and Correlates

An influential developmental theory of empathy is Hoffman (2000)’s model of empathy and moral development. According to this model, the development of empathy progresses in five stages. The first stage corresponds to “newborn reactive cry” which develops until 6 months. At this stage,

Empathy, Fig. 1 Dual system model of empathy. (After Heyes 2018)

when the newborn hears another baby crying, he reacts by crying. This reaction is not a simple vocal mimicry but denotes a real affective component. During the second stage called “egocentric empathic distress” which lasts until the end of the first year of life, the infant responds to other’s distress with expressions such as making a sad face or crying, and he may feel distressed himself. However, he attempts to reduce his own distress with behaviors such as taking his security blanket or seeking comfort from his parents. At the beginning of the second year, comes the “quasi-egocentric empathic distress” stage. The toddler understands that the other is in distress, he feels it, and may attempt to comfort or help the target by displaying behaviors that may typically be useful to overcome his own distress, but that may not be adapted to address the target’s distress (e.g., the toddler gives his security blanket to another child). The fourth stage, “veridical empathic distress,” develops from the end of the second year, when the toddler understands what people feel and that his internal state is distinct from others’ internal state. He is also able to take the perspective of others. Accordingly, he can adapt his behavior to the perceived needs of the distressed target. The last stage is coined “empathic distress beyond the situation.” Between age 5 and 8 years old, children can understand that people feel emotions in general contexts of life and not only in the

immediate situation. They can empathize in reaction to sad life conditions (e.g., feeling sad for homeless people). Over time, as children’ understanding of emotions becomes more complex, they can empathize and better react in response to others’ distress. This developmental model is focused on empathy toward distress, because Hoffman (2000) conceptualized it in a progression of moral judgment in which negative emotions are particularly considered. However, empathy could also address positive emotions, such as happiness (Sallquist et al. 2009).

Several studies have investigated the role of empathy in children’s emotional and social development. Empathic skills favor prosocial behavior from early age (Zahn-Waxler et al. 1992a) and cooperation with peers at preschool age (Jolliffe and Farrington 2006b; Zahn-Waxler et al. 1992a). Empathy is also positively linked with emotion regulation (Lucas-Molina et al. 2018) and higher-level of moral reasoning (Eisenberg et al. 1991). In adolescence, better affective empathy skills lead to constructive problem solving in conflict contexts (de Wied et al. 2007), whereas better cognitive empathy skills help to improve friendship quality (Chakrabarti et al. 2006). Conversely, poor empathic skills were identified as risk factors for proactive aggression in school-aged children (Deschamps et al. 2018) and adolescents (LeSure-Lester 2000).

Other studies reported that empathy and Theory of Mind (ToM), defined as the understanding of own and other's mental states (Flavell 1999), are positively linked (e.g., Wang and Wang 2016; Eisenberg et al. 2006), as they develop simultaneously and recruit common brain regions (Decety 2010; Dvash and Shamay-Tsoory 2014). However, there are some controversies as to whether empathy, especially cognitive empathy, and ToM correspond to the same (e.g., Blair 2005) or distinct constructs (e.g., Wang and Wang 2016). When considering the latter, it remains unclear which construct is antecedent to the other. In fact, it is likely that the nature of this relationship is bidirectional. For instance, in studies focused on the adolescent years, it was both observed that empathy predicts ToM and that ToM predicts empathy (Aliakbari et al. 2013). However, as these studies are cross-sectional, no inferences on causal link and directionality can be made, and more studies are needed to decipher the nature of the relationship between these constructs. Moreover, the relation between empathy and specific mental state related to ToM, such as thought and desire, should be investigated.

Protective and Risk Factors in Empathy Development

In order to identify factors that could be the best targets for intervention, it is essential to examine the factors that contribute to empathy's "natural" development. Further, in contrast to stable factors on which it is challenging to act, there are some more state-like and malleable factors that are more prone to intervention. In typically developing children, stable individual factors include genetic factors (Warrier et al. 2018), gender (Zahn-Waxler et al. 1992b), or temperament. Among more malleable factors, language is a predictive factor of empathy (Rhee et al. 2013) on which interventions can be useful. Family factors, which are the most studied factors, include attachment relationship (Futh et al. 2008; Kestenbaum et al. 1989; Stern and Cassidy 2018), emotional expressiveness of parents (Zhou et al. 2002), parental strategies of emotions socialization (Taylor et al.

2013), in particular conversations about emotions with the child (Brown and Dunn 1991; Dunn et al. 1987), educational style (Miller et al. 1989), and the child's relationship with siblings (Brown and Dunn 1992).

Among risk factors leading to potential deficits in empathy, there are several psychopathological diagnoses and developmental disorders, including autistic spectrum disorder (ASD), conduct disorders (CD), or intellectual disabilities. Specifically, according to the empathy imbalance theory (Smith 2006, 2009), individuals with ASD present deficit in cognitive empathy and an intact affective empathy, while the reverse is observed in individuals with CD, that is, a deficit in affective empathy and an intact cognitive empathy. Future research on non-typically developing populations could further help nuance functional and developmental processes at play in empathy and support the development of intervention guidelines.

Measures

To study empathy and better monitor the effect of empathy prevention and intervention programs, a range of measurement methods were developed, including observational methods, performance-based, or other-reported and self-reported questionnaires that may be more or less adapted to the study population of interest depending on their developmental level. For infancy and early childhood age, standardized situations are commonly set up to elicit empathic reactions. For example, the experimenter or the mother feign to hurt himself or herself (Zahn-Waxler et al. 1992a), to feel sick (Sigman et al. 1992), or to receive a present (Sallquist et al. 2009) without prompting the child to respond. Spontaneous empathic reactions of the child (e.g., verbal or physical comfort, help, giving advice, facial, or verbal expressions demonstrating concern) are noted by using an observational coding grid to obtain an empathic score.

Empathy in preschoolers and schoolers is often assessed by performance-based measures eliciting the child responses to short stories illustrating situations designed to induce emotions, such as

happiness, anger, sadness, and fear (Bensalah et al. 2016). After each story, the child has to answer questions tapping into different components of empathy such as: (a) comprehension (e.g., “*What’s happened to the character?*”); (b) questions about how the child is feeling (to evaluate affective empathy); and (c) questions prompting the child to explain why he feels such emotion (to evaluate cognitive empathy). The measure conceived by Bensalah et al. (2016) evaluates also prosocial behaviors (e.g., give an object, play, help, tell joke) in different situations in which the target feels positive or negative emotions, by asking the child “*What would you do if you were next to the little boy/girl?*”

With other-reported questionnaires, parents and/or teachers rate their perception of their children’s or adolescents’ empathy abilities in daily life. The *Empathy questionnaire* (EmQue, Rieffe et al. 2010), targeting infants and preschoolers (from 1 to 5 years old), gives a global score of empathy as well as scores corresponding to the first developmental levels of Hoffman’s model, namely “emotion contagion,” “attention to other’s feelings,” and “prosocial actions.” For preschoolers, the *Dispositional Positive Empathy Scales* (DPES; Sallquist et al. 2009) and *Empathy and Theory of Mind Scales* (EToMS; Wang and Wang 2016) also offer a global empathy score. *Griffith Empathy Measure* (GEM; Dadds et al. 2012) yields a cognitive and affective empathy score, as well as a global score, and is adapted for children from 4 to 16 years old.

Self-reported questionnaires may be completed by individuals from late childhood to adulthood and refer to their own empathic skills in daily life. The majority of these questionnaires measure distinctly affective and cognitive empathy and often yield a global empathy score (e.g., *Basic Empathy Scale*; Jolliffe and Farrington 2006a). Some instruments include additional scales such as a “prosocial motivation” scale in the *Empathy Questionnaire for Children and Adolescent* (EmQue-CA; Overgaauw et al. 2017), or a sympathy scale in the *Adolescent Measure of Empathy and Sympathy* (AMES; Vossen et al. 2015). These scales, together with recent developments in empathy measures,

could support new research furthering the analysis of profiles of empathy across different periods of life and help monitor progress under the effect of intervention programs more closely and distinctively.

Interventions

Empathy expands the array of possibilities we are endowed with to understand other people. As illustrated above through the presentation of a developmental model of empathy (Hoffman 2000), empathy is not a static entity, and it can therefore be nurtured or trained to address empathy difficulties in children at risk to develop behavior disorders or with autism spectrum disorder. However, with an increased understanding of the underlying mechanism of change used by empathy trainings and interventions, empathy programs could be applied more broadly as a way to cultivate this possibility skill. The same way skills like cooperation, creativity, or critical thinking have been targeted as “21st century skills” to be nurtured and developed (Trilling and Fadel 2012), schools could encourage empathy as fundamental possibility skill which contributes to augmenting our understanding of the world and of each other. Indeed, contemporary beliefs suggest that, in our modern information society, people are becoming less empathetic than previous generations (e.g., Borba 2017), in a context of technologization of human relationships, and increased mistrust and hostility (e.g., new forms of harassment and bullying). Hence, encouraging empathy beyond “treating” an empathy deficit could represent an avenue of transformative change.

Before such broader applications be considered, understanding the main features of effective empathy interventions is pivotal. Several kinds of interventions targeting children from early childhood to adolescence exist, including school-based, parenting-based, and experimental programs. Transversally, empathy trainings are more effective earlier in children development to promote social emotional competences (Malti et al. 2016).

In school-based programs, different constructs such as empathy, perspective taking, emotion understanding, and prosocial behavior are trained in classroom settings. However, none of these training programs focused only on empathy (for a review, see Malti et al. 2016). For example, *Second Step* (Frey et al. 2000) proposes lessons on identifying and understanding emotions in self and others, considering others' perspective and responding emotionally to others. To promote these competences, teachers or external speakers teach children to recognize physical, facial, and verbal cues related to emotions, interpret emotional expressions, and acknowledge different perspectives and reactions in social situations (Frey et al. 2000). Different strategies and materials are used in these kinds of lessons such as reinforcement, sharing personal experience, stories, videotapes, pictures, discussion, and role-play (Bierman et al. 2010; Frey et al. 2005). Results of studies testing such programs showed improvements in empathy, social emotional skills, and prosocial behavior (Low et al. 2015) and a decrease of behaviors disorders (Malti et al. 2016).

Parenting programs are developed to support mothers and fathers' competences, and, in turn, to promote indirectly emotion regulation, empathy, and prosocial behaviors in children (Havighurst and Harley 2007). For example, *Tuning into Kids* (Havighurst and Harley 2007) teaches parents to recognize children's positive behaviors, to change their beliefs and behaviors toward emotion to create more emotional connection with their children, and to stimulate children's language and knowledge about emotion. To do this, lessons are based on emotional coaching (Gottman et al. 1996) and train parents using videotapes, role-play, personal experiences, diverse exercises, and principles of psychoeducation (Havighurst and Harley 2007).

Finally, experimental training program of empathy refer to innovative methods to improve empathy, such as a recent line of programs using Immersive Virtual Reality (IVR) technology. One of the feature of IVR is that it elicits embodiment, through which the user literally experiences the perspective of someone else (Puvirajah and Calandra 2015; Shin 2018) to the extent that the other's body (i.e., avatar) is being experienced as

being their own (Maselli and Slater 2013; Petkova and Ehrsson 2008). This experience resembles cognitive empathy (e.g., providing the experience of another's perspective) and can therefore be encouraged through enhanced simulation programs using IVR. In this line, Herrera et al. (2018) showed that actual empathic response (here, helpful initiatives toward the homeless) was larger using an IVR perspective-taking program compared to less immersive perspective-taking conditions. Further, IVR can be used to simulate situations that trigger emotional responses (i.e., involving content scenario such as homelessness, or racial prejudice), leveraging the likelihood of an empathetic response. For instance, Shin (2018) used an immersive storytelling approach to bolster empathy and highlighted the role of high quality and relevant content to do so. Hence, by supporting both cognitive and emotional processes involved in empathy, together with other mechanisms (for a review, see Barbot and Kaufman 2020), IVR has the potential to elicit empathetic response in real life (Herrera et al. 2018) at a point that it has been touted as "ultimate empathy machine" (Milk 2015). As outlined above, using this empathy machine as a prevention rather than intervention tool represents a promising direction to cultivate the possible within self and society.

Conclusions

"Empathy is the binding substance of the human relationship by which people transmit their culture, their humanity" (Keefe 1976, p. 10). However, contemporary beliefs suggest that, in our modern information society, people are becoming less empathetic than the generations before them (e.g., Borba 2017). Hence, it becomes increasingly critical to understand the nature of empathy, its development, and ways to nurture it. While offering an overview of these important issues, this entry outlined a few important directions for future research in this field. They include, but are not limited to, (1) furthering the analysis of individual's profiles of empathy (i.e., accounting for the multidimensional nature of the construct), which supposes (2) the development of age-

appropriate measures that account for this dimensionality and which will also (3) help track more comprehensively the “natural” development of empathy, as well as (4) change in empathy in response to prevention and interventions programs. With respect to the latter, (5) development of IVR-based programs shows great promise for the generations to come (likely to increasingly adopt IVR technology). More broadly, (6) further longitudinal studies of (multidimensional) empathy are needed to decipher causal link and directional inferences on the relationship between the empathy facets, so that its developmental dynamic can be better understood, and strategies of prevention and interventions developed accordingly. All together, these efforts will contribute to a better understanding of empathy’s nature (e.g., solidify a unified definition), its development and nurture, as a fundamental possibility skill.

Definition

Power, understood as the control over material goods, intellectual resources, and ideology, is a central debate in political and social sciences. In the context of the Global South, discussing power cannot be separated from a strong critique of the Anglo-European hegemony established during

the conquest and colonization of Africa, America, and Asia beginning in the fifteenth century and continuing to the neoliberal economies of today. The concept of *empowerment* emerged consequently as an essential constituent of diverse political and pedagogical agendas from oppressed and colonized groups to create alternative possibilities of existence for building projects of democracy and citizenship. Any such analysis reflects the multiple and diverse layers, related to the many conflicts, tensions, possibilities, and hopes that are distinct to the Global South. In this chapter, we will refer to the long history of *disempowerment* for diverse populations of the Global South through racial classification, slavery, territorial dispossession, and colonialism, a *coloniality matrix* that persists up to today. At the same time, we want to highlight the diverse social movements against colonialist oppression and creative search for *emancipation* and *self-empowerment*. There are several ancestral and contemporary resistances, resiliencies, and re-existences emerging around the Global South to recover and recreate powers toward a full realization of a good living; this is to say, having the spiritual and material resources for enhancing life conditions according to diverse cultural backgrounds, cosmovisions, and philosophies. At the end, we will share how some of these experiences have nurtured our own educational *praxis*, giving us the strength to keep dreaming and working for a world full of positive possibilities for all.

Dis-Empowerment in the Global South

The modern history of most populations from the Global South reflects a long and tragic story of *disempowerment* that encompasses the domination and oppression of diverse groups of people through territorial dispossession and enslavement. This in turn resulted in the denial of people's cosmogonies and knowledge alongside a narrative of nonhistory leading to political disenfranchisement, the destruction of local economic structures, and, in general, the deprivation of the material and symbolic enjoyment of their existence. In alignment with Santos (2012), we

understand "the South" as a destination and a condition. It is constituted by social groups and populations who have systematically suffered injustice, oppression, and destruction related to capitalism, colonialism, and patriarchy imposed in the southern hemisphere. This also means acknowledging the existence of "a South in the North," which are the oppressed and marginalized groups in Europe and North America, as well as "a North in the South," made up of local elites who favor neo/colonialist powers that benefit from global capitalism.

The path toward the disempowerment of people in the South began with the colonial discursive invention of Africa, Asia, Oceania, America, and the Caribbean as "a new World," whose territories and inhabitants were depicted as savage, underdeveloped, and primitive, and juxtaposed against the notion of emerging modern Western Europe as the superior and universal civilization model to be followed (Thiongio 1981, 2017; Mudimbe 1988). This superiority/inferiority binary unleashed harsh dysfunctions against humanity, such as the right to conquer, enslave, colonize, and exploit entire territories and people, breaking communitarian ties, collective property, and non-vertical forms of governance, imposing an hegemonic power that profits from extractive economies to the modern day (Kame'eleihiwa 1992; Sing'Oei 2007; Salas 2018).

A modern and capitalist Eurocentric system based on the constitutive idea of "race, sex, and class" emerged as an instrument of classification and social control (Rodney 1982; Fanon 2011). It became embedded in a patriarchal system inherited from antiquity and consolidated century after century by different powers in Christian Europe (Varela 2005). Thus, the colonial and modern episteme can be described as an ongoing ideological process, grounded in the notion of one race, one sex, and one class as the "superior" and "universal" one: male, white, and paterfamilias, functionally, heterosexual, owner, and law maker (Segato 2011; Sierra and Amariles 2021).

As Aimé Césaire (2000) has stated, colonialism dehumanizes the colonizer and the colonized. The former colonies, then the new republics or nation-states, employed narratives of freedom and

independence in the name of a plural society. But once independence was achieved, the colonialist, patriarchal, exploitative, racist, sexist, and segregationist structures were merely reedited and reproduced, giving continuity to segregation and oppression. Although most of the emerging republics based their new government policies on revolutionary postulates such as the prohibition of human trafficking and enslavement and the nonexpropriation of communal territories through the installation of neocolonial administrative models, extractive economic patterns, private land property, centralized educational systems, and an imposed unique religion and language, there was no room for the polyphony that had been fought for to develop independence and freedom. What emerged was an elite “North in the South,” constituted by heirs of *imagined whiteness* that maintained privileges in the access to education, and a disproportionate share of resources, while racialized and marginalized populations remained deprived of access to opportunities of schooling, land, and resources. This in turn laid the foundations of multiple social disparities and armed violence of today.

A racist, sexist, and classist educational model persists in the Global South despite glimpses of social and educational transformation resulting from various emancipatory social movements during the twentieth century. Movements that have not been vigorous enough to *decolonizing the mind* understood as the constant critical, transgressive, and insubordinate viewpoints and ethics toward transforming colonialist and exploitive power relationships in all aspects of life: institutions, cultures, knowledges, values, aesthetics, languages, religions, and ontologies, among others (Thiong'o, 1981; Lander 2000; Mbembe 2016; Kgatla 2018).

The Coloniality Matrix

There are not words to describe how colonialism and capitalism, hand in hand with all their exploitive and dehumanizing heritage, have affected the life of millions of women, men, and children in the Global South. How to honor in this short space

the diverse voices that have denounced and keep denouncing this insanity? How to give account of the enormous tensions and contradictions but also the solidary similarities across the varied different interpretations, action research, and studies (post-colonial, decolonial, subaltern, anti-racist, anti-colonial, feminists, African, Asian, Latino, Indigenous, and Mestizo, among others)? There is an ongoing critical dialogue on all these different approaches, but it goes beyond the purpose of this chapter to describe it. Just to give a glimpse of the complex discussions contrasting perspectives see Adichie 2009; Bhambra 2014; Asher 2017; Ndlovu-Gatsheni 2020.

Nevertheless, we consider Walsh's (2012) description of *the coloniality matrix* very useful here to explain the complex process of colonialist disempowerment. It offers a comprehensive route to understand the interconnectedness of coloniality's main axes: the coloniality of power, knowledge, being, and nature (see Graphic 1).

The *coloniality of power* refers to the establishment of a system of social classification and exploitation of labor based on a hierarchical racialized division, with the Europeanized male at the top. The *coloniality of knowledge* positions Eurocentrism as the exclusive order of reason, knowledge, and thought, discarding and disqualifying existence and viability of other epistemic rationalities or cosmovisions. We understand cosmovision as a particular way to see the world and to give an order to the cosmos and universe, considering as reference diverse communities' comprehensions of culture or people, their historical dimensions, imaginaries, representations, and practices. Subsequently, cosmovision is closely associated to the ways indigenous, Afro-descendent, and peasant peoples from the Global South comprehend and live in the territory, a vital space that assures their survival as peoples in a very deep interdependency to nature, humanity, and spirituality (Estermann 2021; Quintari and Quiñonesii 2016; Escobar 2016).

The *coloniality of being* is exercised through inferiorization, subalternization, and dehumanization of beings who, because of their skin color and ancestral non-Christian roots, are considered lacking soul and reason. Finally, the *coloniality*

Empowerment, Graphic 1 The coloniality matrix, own graphic from Walsh (2012)

of nature refers to the binary division nature/society from which exploitation and control of nature is justified, denying cosmovisions that see it as the mother of all beings (Walsh 2012). For a further discussion on how this division nature/science emerged in modern sciences, as well as a critique to the gender/science system, see Keller (1991) and Harding (2000). On the inextricable connection of the mother earth's conception with the language culture and territory of Indigenous people, see Green (2011).

The coloniality matrix requires also an intersectional perspective to understand how socially and culturally constructed categories such as race/ethnicity, social class, or gender function in an interrelated and interdependent way. *Intersectionality* is a conceptual category developed by the African-American feminist Kimberlé Crenshaw (1989) referring to the experience of multiple discriminations suffered by African-American women in both the African-American and feminist movement. Hence, the relevance of the notion of *coloniality of gender*. This concept was put forward by Latin American feminists

such as María Lugones (2008), acknowledging the multiple oppressions that are generated and reproduced by the modernity/coloniality system, in which gender and race are instruments of power that intersect one other.

Deconstructing Colonialism and Coloniality

While colonization supposes an imperialistic and structural domination including violent undertones over a large heterogeneity of people (Mohanty 2008), coloniality can be defined as the capability of power structures to survive the demise of the underlying juridical administrative processes and so evading the fundamental changes desired by anti-systemic movements. Colonialism keeps influencing all aspects of the lives of its colonized subjects, including their ways of knowing, seeing, and imagining the world (Ndlovu 2018). Decoloniality stands therefore as a pedagogical, political, cultural, and epistemic project that aims to deconstruct *the*

coloniality matrix of power, knowledge, being, and nature. It emphasizes the constant creative process of unveiling historical oppressions and exploitation among humans, and the depletion of the natural world, to rethink alternative ways of existing in the planet (Walsh 2013).

Postcolonial studies offer theoretical foundations that contribute to comprehend power and empowerment from the Global South. They do not merely state a temporary differentiation and disruption between colonization and independence, but they propose a clear stance on the role of colonization and imperialism in the imposition of the reality we have today. Above all, postcolonialism establishes a plural perspective from the South toward the construction of modernity and history. That is to say, modernity not as a lineal Eurocentric narrative, but as a complex construction in several places of the world. It encompasses the idea of critically moving from history to histories, interrogating universality and homogeneity. Following this process postcolonial studies highlight the sense of place of the subjects from the Global South: How their *insurreccional capacities* take a more decisive place in global narratives (Mezzadra 2008)?

Both postcolonialist and decoloniality critiques invite us to *transform the coloniality of knowledge* in the following ways. First, through disassembling the deep Eurocentric knowledge structures, which are hegemonic within the education “national” systems of the South. Second, *transforming the coloniality of power* by disrupting monopoly powers over land ownership that would strengthen social organizations to encourage the participation of each society member in political decision-making. Third, *transforming the coloniality of being* by finding innovative ways of educating individuals and social groups to confront the oppression of patriarchy and racism that persists in society, recognizing the challenges that such a pedagogical process might be (Martinez 2014; Viveros 2019). Finally, transforming the *coloniality of nature* means fighting against predatory extractive economies, questioning the vision of nature as a resource to be exploited, acknowledging cosmovisions that do not separate humans from

nature, and instead, recognizing nature as a subject of rights (Ebus 2017; Laastad 2019).

Educational Experiences Toward Empowerment from the South

An ethical-political perspective on “empowerment” from the Global South means transforming power structures that exploit people and the natural environment to recognize the inhabitants from the South as subjects and not objects of history. Thus, *Surear* or “Southering” means creating pedagogical and educational possibilities to reconstruct society members to transform colonialist realities for the defense of a caring of life (Espinosa and Calderón 2020). It means learning from communitarian and resistance experiences recreated in the South, to problematize unjust realities and envisage a genuine, humanistic world.

Today, we can find several transformative educational efforts to change oppressive realities and create alternatives away from the coloniality matrix. Just to mention a few: *Pedagogies of Re-existence* (Achinte 2009); *Insubordinate Pedagogies* (Medina 2015), and *Education for a Possible World* (Santos and Meneses 2018). They have in common building the power in search of a good living for all. A good living differs from consumerist perspectives; instead, it is related to what Andean Indigenous communities understand as “Sumak Kawsay” or “*Buen Vivir*” (Living Well) (Kowii 2018), the Colombian Pacific African diaspora in Chocó as “*Vivir Sabroso*” (Living in harmony with nature, spirits, and human beings) (Quiceno 2016; Mena and Meneses 2019) or the Peasant Mestizo movement as “*Vivir con dignidad*” (The right to live in dignity) (La Vía Campesina, in Hubert 2019).

Following, we will share briefly our own educational practices, which have been nurtured by these different discussions and perspectives:

1. Ximena Amariles’ (2020) project “*A face with different voices. Contributions of peasant women to a critical intercultural pedagogy*” aimed to understand the complex interweaving

that connects coloniality with patriarchy through the narratives of peasant women who belong to the Association of Peasant Women of Rionegro (Así Mujer), a municipality in eastern Antioquia, Colombia. The linking of women to the organization since 2010 has become a political educational process that has contributed to recognizing other ways of understanding and inhabiting the world, based on the voices of peasant women as a central axis and mobilizer of other possible realities – not oppressive ones – by the construction *from below and from inside*, the dialogue of knowledge, the strengthening of unity between women, and the generation of solidarity to contribute to the good life of both women and peasant territories. This local experience is part of a larger dialogue with other feminist movements such as the Popular Education Network among Women from Latin America and the Caribbean – Red de Educación Popular entre Mujeres de América Latina y el Caribe (REPEM) and the Rebellion Scarves (Pañuelos de Rebeldía). These scenarios enhance feminist popular education work for the promotion of gender equality and equity, the exercise of citizenship and human rights, and the political, social, economic, and cultural participation of women in all aspects of society (Torres et al. 2010; Arana and Rapacci 2013).

2. María Eugenia Morales (2019)'s participative action research was aimed to make visible Afro-descendent women's own political, educational, and resistance processes and their demand for rights within a very racist, classist, and sexist society, and also to reveal how Afro-descendant women's ancestral political practices have served their own people and society in general, thus reinforcing interculturality. Her study was based on a former project for the creation of the first trade union of Afro-Colombian women domestic workers. It included an anti-racist and anti-patriarchal analysis of society to explore the problematization of a racialized systemic structure that intersects the conditions of sex, gender, class, and race imposed on the bodies of Afro-Colombian women (Morales et al. 2013). As a result, this organizational process has impacted very positively on these women's personal and community lives, particularly the recognition and appreciation of their Afro-descendant identity, knowledge, and culture.
3. Despite the conditions of subjugation and marginalization, Afro-Colombian women have developed very creative pedagogical and educational strategies for organizing themselves through the historical figure of *marronage*. *Marronage* implies cultivating solidarity, applying extended family values, and strengthening affective ties to help and offer hospitality to each other. It has contributed to make visible how Afro-descendent women in domestic works recreate, negotiate, and teach their own ancestral knowledge about food, values, upbringing, dance, music, and language to the families they work for. This organizational process contributed to participants' own recognition of their own strengths and agency for entrepreneurship and empowerment, what Arboleda (2016) calls the *intimate sufficiency*, how each human collective and person possess the capacity to create and to imagine; therefore, they have the basis to build and exercise power.
3. Yeison Meneses's (2020) research work entitled: "El río sigue siendo el río" (The river continues to be the river). "Childhood and intersectional resiliences: *des/obligamientos* in the state of Chocó, Colombia, 1991-2020" was oriented to the comprehension of the intersectional resilience processes in children, girls and boys, who have been *des/obligados* (uprooted, as forced displacement survivors) by the armed conflict taking place in the state of Chocó, Colombia, during the last three decades. Meneses's main effort was to present the *des/obligados* not merely as victims but as historical, intellectual, creative, and empowered people. He analyzes the intersectional resilience's processes: collective and individual strategies, psychological conditions, familiar surroundings, educational environment and support networks, communitarian values, cultural backgrounds, creative developments, and recreational and playful dynamics built and developed by children to face the

appalling effects caused by war. Also, how these children *represent* and overcome traumatic experiences, and restart life with hope, enthusiasm, joy, dreams, and future expectations. Meneses (2020) found that the intersectional resilience processes relied on local people's philosophical foundations from their strong relationship with the river and nature, cultural backgrounds, and identity. Alongside this, teachers' pedagogical engagement with social problems relating to the effects of armed conflict and drug trafficking led to the importance of family practices of caring.

To comprehend the dimensions of the role of education and pedagogy in the process of resilience development, the author considered other educational and pedagogical experiences from ethnic-racial and plurilingual perspectives in Colombia. These have grown in territories historically affected by the dominant extractive economic model, the armed conflict, the multidimensional impoverishment, and the social inequalities that highlight the consequences of systematic racism (Múnera 1998a, b). These ethnic educational initiatives are built from the challenges that children born in this biodiverse territory face challenging dangerous experiences when getting to school by swimming across rivers, walking long distances across farms, forests and paddocks, or riding horses when they might encounter armed actors and antipersonnel mines. However, despite the war and displacement adversity, from a very early age, girls and boys develop strong capacities and creative agencies to face life's experiences and opportunities. Thus, the pedagogical initiatives based on the *des/obligados* resistance are seeds of hope and environments of possibilities to foster critical thinking, feelings of belonging, developing solidarity, and strengthening collective thinking, which both question and defy the impositions of capitalist individualism.

4. As described elsewhere (Sierra et al. 2021), the absence of higher education programs relevant to the diverse social, cultural, and environmental rural contexts has led new generations of

rural youth to migrate to cities in search of postsecondary studies and sources of employment in order to finally leave their territories. Education in rural contexts, from a decolonial perspective, can serve to identify and address the different factors that render vulnerable rural communities' rights to live with dignity and challenge the historical causes of social injustice and discrimination. Coauthor Zayda Sierra has been working with other colleagues since 2012 to develop an undergraduate program in *Pedagogy in Rurality and Peace*, to be formally offered by the Faculties of Education and Public Health at Universidad de Antioquia in 2021. With the participation of social leaders, men and women, young and elders, issues relevant to their contexts have been identified, as well as objectives, themes, and guiding questions, reflecting their personal, family, community, and territorial life. A main issue is how participants' different personal interests and common topics might contribute to build and enhance communitarian life projects, promoting participants' capacity for action across different political possibilities, not as passive subjects or mere recipients, but as creators of their own reality.

Some Concluding Remarks

We discussed empowerment as a way forward for society members to decide and make possible a positive future across both the personal and the collective through communitarian, territorial, educational, cultural, and environmental projects. These projects are necessary to go beyond the historical circumstances that have driven a vast majority of the population in the Global South to a situation of disempowerment. The coloniality matrix helps to explain how the economic and political elites have been historically perpetuating their practices through the appropriation of natural resources, imposition of hegemonic knowledge, authoritarianism, and the militarization of society, which in turn has produced discrimination and violence grounded in ethnic, racial, cultural, and gender identities.

However, we must not only look at the dehumanizing construction and invention of the “loss of power or agency” through such prejudiced and discriminatory practices, but also at historical and creative resistances and re-existences. Across all latitudes, we can find numerous emancipatory and liberating pedagogical processes toward empowerment oriented to the reconstruction, recovering, and recreation of *other* cosmogonies and cosmovisions, other ways of seeing and inhabiting the world. These are all educational projects that go outside the four walls of schools to find solutions to the sociocultural challenges each community faces.

To sum up, “the world of possible” implies acknowledging empowerment as part of diverse individual and collective human efforts toward imagining and creating other notions of power grounded in affection, hope, love, joy, and spirituality. This entails building collaborative and solidary initiatives for decolonizing and depatriarchalizing society and so transforming predatory and extractive practices to recognize nature’s rights for a balanced relationship between humans and the natural environment.

Entrepreneurship

Laurice Alexandre
CEPED, Université de Paris, Paris, France

Abstract

Entrepreneurship is a French word which describes the action of undertaking a venture. However, the concept of entrepreneurship is being expressed in other words such as small business. The concept is part of a multi-disciplinary approach: economy, management, psychology, sociology, geography, gender, and education. While the entrepreneur of the sixteenth or eighteenth century was considered as an industrial, an innovator, or a manager,

today the entrepreneur should play a large social and economic role and most of all create jobs. This is in light with Drucker's (1985) definition "*entrepreneurship is the act that endows resources with a new capacity to create wealth.*" Research on entrepreneurship have started with Insudtrials, Economics, and Researchers but gained a lot of interest in Management from the 1970s. Many topics have been addressed such as: the psychological profile, the opportunity concept, the entrepreneurial intention, internationalization, education, business model, intrapreneurship, social and responsible entrepreneurship, gender, and so on.

Keywords

Entrepreneurship · Economics · Management · Research · Process · Opportunity

Introduction

Entrepreneurship is at the heart of the transformation of industrial society and covers varied realities: from the individual who creates a company to escape unemployment, the innovator whose name becomes synonymous with the product he invented and marketed, to large companies that initiated intrapreneurship (Boutillier 2017). The chapter will be articulated around the history of entrepreneurship, entrepreneurship in Economics and Management, research in entrepreneurship, and possible fields to be explored.

A Brief History of Entrepreneurship

Entrepreneurship is not a new concept. According to the legacy of the ancient, Romans stands in stark contrast to that of the enterprising Mesopotamians and Phoenicians. A tribe of "middlemen and merchants" transformed a small strip of land in modern-day Lebanon into the hub of intercontinental trade. Considered one of the ancient world's most entrepreneurial and inventive cultures, the merchant-sailors of Phoenicia connected Africa, Europe, and Asia Minor into a

network of trade so vast and profitable that their success was marveled at by Ezekiel and other authors of the Old Testament (Carlen 2016).

So, the Middle East and Mediterranean Europe were the settings of most of the significant developments in the early history of entrepreneurship. However, by the medieval era, Chinese civilization had not only caught up with those regions commercially but in some respects surpassed both the Islamic world and Christian Europe (Carlen 2016).

More recently, in Britain, the industrial revolution that began in eighteenth century pushed the institutions to reacting to the revolution thanks to inventive British entrepreneurs who did – the “captains” of new industries (Landes et al. 2012).

The United States, particularly during the period from the Civil War until the end of the twentieth century, stands as the quintessential entrepreneurial society. From John D. Rockefeller to Henry Ford and all the way to late twentieth-century information age pioneers like Bill Gates and Steve Jobs, America spawned one iconic and internationally renowned entrepreneur after another (Landes et al. 2012).

In France, Entrepreneurship emerged at the start of the twenty-first century as a national cause. This enthusiasm for entrepreneurship is found in many countries inspired by Schumpeter’s economic thinking. The Schumpeterian thought gave the function of the entrepreneur a driving role in the evolution of capitalism. This political, even societal, recognition of entrepreneurship is concomitant with the recognition of entrepreneurship as a discipline at the confluence of economics, social sciences, and management (Messeghem and Torrès 2015).

However, entrepreneurship cannot be reduced to the creation of a new business, it also could be intrapreneurship, takeover, and spin-off activities. The term intrapreneur has never been explicitly used in McClelland work or Schumpeter, but the entrepreneurial conception includes the intrapreneur. This notion, which appeared in 1976, has often been used without being clearly published (Messeghem and Torrès 2015). The intrapreneur, who behaves like an entrepreneur, has an

entrepreneurial role within an existing organization. Entrepreneurial activity does not therefore necessarily create a business.

On the education level, Kuratko et Morris (2018), declared that Katz (2003) included economic and agricultural literatures and experiences dating back to 1876, while others have touted the Harvard courses taught in 1947. However, the reality of entrepreneurship education in business schools began in the early 1970s. Which matches with the emergence of entrepreneurship education.

Entrepreneurship from Economics to Management

During the centuries, many authors mostly entrepreneurs themselves defined and discussed the entrepreneurship specificities. In most of the studies on entrepreneurship, Cantillon was cited as the first author to publish a book on his experience as an entrepreneur especially in the agriculture field.¹ According to Cantillon “*the entrepreneur is a specialist in taking on risk, ‘insuring’ workers by buying their output for resale before consumers have indicated how much they are willing to pay for it*” (Casson and Godley 2005, p. 26). Marchesnay (2016) stated that Cantillon (1730) called the entrepreneur a venturer or adventurer.

The second author to be recognized as a reference in the industrial entrepreneurship was J.B. Say. In his work, he discussed all the value chain and the marketing strategy to be adapted by an entrepreneur. According to him “*industrial entrepreneurs contribute to production by applying the knowledge acquired, the service of capital and that of natural agents, to the making of products to which men attach a value...It is sometimes a question of bringing into play a very large number of individuals; you have to buy or have people buy raw materials, bring together workers, look for*

¹Olivier de Serres was known also for his work in the agriculture field studies.

consumers, have a spirit of order and economy” (Say 1814, p. 24).

J.B. Say is also at the origin of the Theory of Production which led him to focus on another form of division of labor between the various actors of the production and to bring out the role of the entrepreneur. Thus to him, “for to obtain any product, it was first necessary to study the process and the laws of nature, relative to this product. It was then necessary to apply this knowledge for useful use. Finally, it was necessary to carry out the manual work indicated by the two preceding operations” (Ravix, 2014).

In the twentieth century, Schumpeter changed the landscape by focusing on the innovation and the role of the man as an entrepreneur. To him, the entrepreneur is a man with broad economic horizons and sufficient energy to challenge the propensity for routine and to carry out innovations (Schumpeter 1934). For Schumpeter the entrepreneur can be a director having a desire to be a founder and promoter. It is this last function which best characterizes the function of entrepreneur. Having an ability to motivate. He is above all a leader.

After Schumpeter, the Economic Era started to leave room to other considerations of the entrepreneurs especially in sociology and psychology focusing on the characteristics of the entrepreneur as an individual. The Management era started in the 70th with Gartner and Mc Clelland studies. McClelland’s work paved the way for a whole pan of research in psychology aimed at studying the psychological characteristics of entrepreneurs. This has been the mainstream of research in entrepreneurship until the controversy, in 1988, between Carland and his colleagues who were supporters of the school by the features and Gartner, a defender of the school by the facts (Messeghem and Torrès 2015). At the start of the twentieth century, the role of the entrepreneur through its societal dimension was widely described by Max Weber in *The Protestant Ethics and the Spirit of Capitalism* (Messeghem and Torrès 2015).

Landström and Benner (2010) have pointed three eras of entrepreneurship thinking:

1870–1940 Economic Era

1940–1970 Social Sciences Era

1970–2000 Management Studies Era

As previously mentioned, the 1970s was the beginning of a big interest in studying entrepreneurship from the perspective of the Management field. In 2012, Landström et al. (2012) proposed a classification of the 20 most cited authors in the entrepreneurship field thanks to the J-index: in the first position one can find Schumpeter (1934) followed by Shan and Venkataraman (1982), Shane, Aldrich and Zimmer (1986), Knight (1994), Saxenian (1942), Schumpeter (1997), Venkataraman (1988), Gartner (1965), etc. Interestingly, most of the authors are in the Management field. Only Schumpeter comes from the Economics field suggesting that entrepreneurship has been adopted very quickly by researches in Management especially in the United States. Indeed, the Academy of Management (AOM) has emerged in USA in 1936. Over the years, AOM has evolved from an organization of 10 members to an organization of over 19,000 members from nearly 120 nations. Today, AOM’s 26 professional divisions and interest groups that promote excellence in established management disciplines (Academy of Management website, 2021). In the French speaking countries, two associations were created: AIREPME² (1996) and AEI³ (1998) with the aim of gathering researchers and professionals to promote entrepreneurship by organizing workshops, conferences, research projects, etc. Moreover, each association proposes its own Journal with a high academic ranking.

The Journal of Small Business Management, which started in 1963, was the earliest academic journal in this field. Early articles were more practice oriented (to fit the times), and it was not until 1976 that the American Journal of Small Business

² Association Internationale de recherche en entrepreneuriat et PME (international association for research in entrepreneurship and SME).

³ Académie d’Entrepreneuriat et d’Innovation (Academy of Entrepreneurship and Innovation).

was founded. It was later renamed Entrepreneurship Theory and Practice in 1988 (Kouratko et al. 2020). According to Messeghem et Torres (2015), the entrepreneurship as a discipline has found its expression through the award given to Shane and Venkataraman (2000) for their article in Academy of Management Review, consecrated article of the decade by this major journal in the field of management.

Research in Entrepreneurship

The Paradigm of Opportunity

According to Messeghem and Torres (2015), Small and Medium-sized Entreprises (SMEs) are a privileged object of study, moreover the Anglo-Saxons use the expression “Entrepreneurship and Small business”. The term entrepreneurship has become a generic term that covers research on Very Small Enterprises, start-ups, family businesses, or large companies that favor an entrepreneurial orientation. However, although there is considerable overlap between small business and entrepreneurship, the concepts are not the same. All new ventures are not entrepreneurial in nature. Entrepreneurial firms may begin at any size level, but key on growth over time (Carland et al. 1984). Actually it depends on how these SMEs develop

the “opportunity” on the market. The opportunity paradigm was and still in the core of the development of SMEs and entrepreneurship. It is the way they use the opportunity which will distinguish an SME business from entrepreneurship. In their article, Messeghem and Torrès (2015) summarized different research stream discussing the paradigm of opportunity. The table below presents an adapted version of their work.

Shapero (1975) proposed a model based on the intention process: feasibility and desirability with a propensity to reacting to the opportunities. This concept occupied the entrepreneurship studies in management and was validated and enriched later by different authors (Krueger, Ajzen and Fishbein, Ajzen, etc.) (Table 1).

Typology of Entrepreneurs

The main discussions in different studies are about the psychological traits of the entrepreneurs. A recent typology has been developed by Alexandre (2016) that shows the evolution of the definition of the entrepreneur since Savary in the sixteenth century (Table 2). As described in the Table 2, the entrepreneur profiles evolved during the years and adopted socio styles when in the beginning, the authors emphasized more the features of the individual and their managerial skills.

Entrepreneurship, Table 1 Stream research in entrepreneurship paradigm and opportunity

Stream	Founding authors	Consideration of the opportunity
Economic school	Schumpeter, Kirzner	The pursuit of an opportunity is carried out by a entrepreneur whose function is to contribute to market equilibrium or imbalance
School of Traits or psychological school	McClelland	Certain traits can promote ability of the entrepreneur to perceive the opportunity and influence their propensity to exploit it: Self efficacy, locus of control
Decision school or cognitive school	Shapero, Krueger	The mental processes that lead to identify or create and exploit opportunities
Process school or behavior	Gartner	The emergence of organizational structure that supports identification and exploitation of the opportunity
School of Entrepreneurial Organization	Stevenson, Burgelman, miller	How do existing organizations do they come to identify or create and operate carlandopportunities?
SME school	Torres and Julien, Messeghem, Torres, Zhara and George, etc.	Specificities of the SME, modes of governance and management adapted to this type of organization. But also the opportunity and international entrepreneurship

Adapted from Messeghem and Torrès (2015)

Entrepreneurship, Table 2 Typology of entrepreneurs since the sixteen century

Authors	Period	Typologies
Savary	XVI ème century	The entrepreneur is a perfect trader
Cantillon	(1697–1734)	Manager of production and trade, who bears, alone, the risks linked to market constraints and price fluctuations.
Say	(1767–1832)	The entrepreneur is the farmer, the manufacturer, the trader, or, to designate them by a name common to all three, he is the industrial entrepreneur. The entrepreneur is one who “undertakes to create for his own account, for his benefit and at his own risk, any product”. The entrepreneur is above all an organizer. It brings together and harmonizes the factors of production, to create the framework and conditions for optimal utility.
Schumpeter	1935	The entrepreneur is a “disruptor and innovator,” they are gifted with imagination and show initiative and willpower
Cole	1942	Four types of entrepreneurs: 1. The practical entrepreneur 2. The informed entrepreneur 3. The sophisticated entrepreneur 4. The mathematically articulated entrepreneur
Smith	1967	Two types of entrepreneurs: 1. The craftsman 2. The opportunistic entrepreneur
Collins et Moore	1970	Two types of entrepreneurs: 1. The administrative contractor 2. The independent entrepreneur
Laufer	1975	Four types of entrepreneurs: 1. The manager or the innovator 2. The growth-oriented entrepreneur 3. The efficiency-oriented entrepreneur 4. The artisan entrepreneur
Miles et Snow	1978	Four types of entrepreneurs: 1. The prospector 2. The innovator 3. The follower 4. The reactor
Vesper	1980	At least 11 types of entrepreneurs: 1. Self-employed working alone 2. Team builders 3. Independent innovators 4. Multipliers of existing models 5. Operators of economies of scale 6. Capital raisers 7. Acquirers 8. Artists who buy and sell 9. Builders of conglomerates 10. Speculators 11. Apparent value manipulators
Julien et Marchesnay	1987 1996	Two types of owner-managers: 1. PIG (sustainability, independence, growth) 2. GAP (strong growth, autonomy, little perpetuation)
Carland, Hoy, and Carland	1988	Two types of organizational actor: 1. The entrepreneur 2. The SME owner

Entrepreneurial Process and Business Model

The entrepreneurial process takes a large importance in the literature on both academic and professional levels. Three entrepreneurial processes are in competition: the effectuation, the causation, and the Lean startup approach.

Sarasvathy (2001) made a distinction between effectual and causal entrepreneurship. “*Causation processes take a particular effect as given and focus on selecting between means to create that effect. Effectuation processes take a set of means as given and focus on selecting between possible effects that can be created with that set of means*” (Sarasvathy 2001, p. 245). It is common in the literature to think that effectuation is more appropriate for women especially in developing countries because they have to undertake with the available means.

In the literature, many researchers adopted the causation process, but many others considered causation as very academic and which doesn’t take into consideration the environment. This competition was translated by the development of the business model in numerous works

proposing very different definitions. Some of them give more importance to the value, others to the resources, etc. Ghezzi (2020) provided different definitions of the business models.

Recently, another entrepreneurship process has emerged (Ries 2011) called a lean startup approach. Its aim is to offer agility to the startups based on the principle of continuous innovation and the possibility to constantly adapt not only its offer but also its company to changes in the market.

On the other hand, more and more research is being hold on gender entrepreneurship because till now, most of the researches discussed the entrepreneurship as it was genderless or even oriented to men. Alexandre (2016) showed a gender distinction of the characteristics of entrepreneurs according to the literature (Table 3). Even though, some of them have been refuted during the years by the researchers who showed that the environment (institutional, socio-cultural, and the education) plays an important role in shaping the characteristics of the entrepreneurs and sometimes there are no differences between men and women.

Entrepreneurship, Table 3 Characteristics of entrepreneurs men/women

	Men	Women
Motivations	Push	Pull
Management style	Vertical	Participative
Risk aversion	Moderated	High
Values	Profit	Family and CSR
Networks	Professional	Social and family
Obstacles	Market and competition	Funding, support, and sociocultural environment
Activity sectors	Industry/technologies	Service and social

Source: Alexandre (2016)

The Possible in Entrepreneurship Research

Even if Entrepreneurship as a discipline is considered as mature, many concepts are yet to be explored. Fayolle (2017) proposes four perspectives to be taken into account:

- Redesigning entrepreneurship research (more qualitative than quantitative, developing entrepreneuring concepts, etc.).
- Crossing fields and concepts (to develop a feminist perspective of the entrepreneurship concept (Henri and Marlow), to develop research at the crossroads of entrepreneurship and education, crossing entrepreneurship and culture, crossroads of entrepreneurship and family business).
- Embedding knowledge in insightful concepts and domains (Entrepreneurial orientation and whether it is a managerial disposition, a behavioral phenomenon, or some combination of the two. Read and Dolmans propose a number of directions to improve the knowledge on effectuation around the concept itself, its antecedents, conditions, and consequences. Psychology, together with economics and sociology, can be considered as a “parent discipline” for entrepreneurship).
- Exploring new or revisiting old research topics: study of rural Enterprise, reexplore the concept of incubators, exploration of illegal entrepreneurship into rural entrepreneurship and seven key questions that are to be asked in an entrepreneurial decision-making paradigm: who, when, where, what, why, how, and what for (Fayolle 2017).

The major themes that characterize recent research about entrepreneurs and new-venture creation are increasingly reflected in entrepreneurship education: opportunities and the entrepreneurial process, venture financing, entrepreneurship research, education and pedagogy, global entrepreneurship, women and minority entrepreneurship, social entrepreneurship and sustainability, corporate entrepreneurship, family business, economic development and entrepreneurship, entrepreneurial cognition (Kuratko and Morris 2018).

Studies on the contextual entrepreneurship especially on women in developing countries are still shy despite the fact that in these countries women participate to improve the household’s living standards thanks to their entrepreneurial activities, even though in most of the times the activity is being hold is in the informal sector. That is the reason why the different governments are encouraging women entrepreneurship especially in the formal sector in order to make them a role model to other women. Fritsch et al. (2019) suggest that new business formation and entrepreneurial role models accelerate future entrepreneurship, particularly in areas with high levels of entrepreneurship due to the aforementioned mechanisms of self-perpetuation. Based on the mechanisms described above, past entrepreneurship fosters the self-perpetuation of entrepreneurship via promoting cultural attitudes among the local population, which are more predisposing to entrepreneurship.

Future research should be oriented toward topics including social business, education, sustainable agriculture, etc. Indeed, if entrepreneurship is the product of individual initiatives, these are contextualized, and fit into social practices in

which a wide variety of actors intervene: public authorities, large companies, research centers, universities, support structures for business creation, but also family dynamics which remain important today (Boutillier 2017).

Finally, the COVID crisis pushed the companies especially the small ones to accelerate the digitalization transformation. It could be interesting to study how the digitalization may affect a company's performance and their international development. The crisis has also provoked a lot of stress and anxiety to entrepreneurs and employees. In France, it exists already an observatory studying the health of entrepreneurs, but a lot of studies still need to be hold in this topic.

Conclusion

Entrepreneurship today is everywhere, across campuses, across communities, and across borders. With the dramatic advances in entrepreneurship scholarship, academic programs, and pedagogy over the past 40 years, there is no question the discipline has achieved academic legitimacy (Kouratko et al. 2020).

In France, in 2013, public universities have created the status of national student entrepreneur⁴ in order to encourage the students to create their venture. The PEPITE⁵ offer students a network and an incubator in order to accompany them during their entrepreneurship activities but also to train them and help them have some fundings. Some of them (those who are not issued from business, they can have an entrepreneur diploma which allows them to continue working on their project after their studies and having a recognized title. This network is meeting a lot of success and is being developed now in different countries and even the

AUF⁶ is a main partner to developing this activity in developing countries.

On the international level, entrepreneurship is becoming a competitive factor between countries. There are many reports proposed by the OECD, the Global Entrepreneurship Monitoring (GEM), and Doing business, with the purpose of providing some recommendation to the countries especially with regards to women entrepreneurship.

Department of Developmental and Social Psychology, University of Padova, Padova, Italy

Errare humanum est

Keywords

Error · Lack of information · Measurement error · Stochastic error · Uncertainty

Synonyms

Lack of information; Measurement error; Stochastic error; Uncertainty

Definition

Error is the lack of ability in explaining empirical phenomena. It can be classified in many ways, depending on the context. In human behavior, it could be considered an unintentional deviation

from a desired aim. In measurement issues, the main distinction is between random and systematic errors. In a statistical sense, it could be viewed either as a result of a measurement process – usually represented as a stochastic process – or as a lack of information about the data generation process. In applied sciences, modeling the error is a relevant source of knowledge and, generally, one of the main aims is to measure or control it.

Error is part of life. For example, we can think of how evolution works: For instance, transcription errors in the DNA – when they produce favorable mutations – contribute to the change of species. Similarly, we can think about those errors that lead some researchers to new scientific discoveries, such as in the case of penicillin or dynamite.

The concept of error is also closely related to randomness. Indeed, all natural phenomena show stochastic properties, which render their outcomes difficult to predict (e.g., long-term or large-scale processes).

Errors can be classified either as behavioral, that is, a deviation from a behavioral norm (Merriam-Webster 2021), or as a function of something being measured. In the first case, we use the term *mistakes* to indicate a deterministic violation, whereas in the second case, we use *measurement errors*, a slightly different terminology to indicate a more complex phenomenon.

Measurement Errors

Measurement error is the difference between empirical measurements and their true value, i.e., *measurand*; (Dodge 2003). It is defined as $y = \eta + \epsilon$ where η is the measurand and ϵ the related error. In this context, ϵ quantifies the uncertainty of knowing η . More generally, the Guide to the Expression of Uncertainty in Measurement (GUM) – a systematic of the Joint Committee for Guides in Metrology (for further details, see <https://www.bipm.org/en/home>) – makes a precise distinction between errors. In particular, GUM suggests to differentiate between two sources of uncertainty, which are the basis of what we commonly call errors: type-A and

type-B uncertainty. By and large, type-A uncertainty corresponds to a statistical analysis of measurement uncertainty through which we identify random or systematic errors affecting the measurement process (systematic errors are commonly recognized as biases in measurement). By contrast, type-B uncertainty comprises all those sources which depend upon general measurement conditions, such as previous measurement data and the experience with the object being measured. The first type of uncertainty is something related to the precision of a measurement, whereas the second type relates to the accuracy of the measurement process.

Systematic and Stochastic Errors

In measurement-related applications, an important distinction is made between systematic and random errors. An example will clarify this difference. Imagine that we are going to measure the weight of a given object, for instance, a coffee table, and suppose we know its true weight η in advance. To quantify the weight, we use measurement tool A . If we could measure the table weight repeatedly – for instance n times – we would obtain a collection of measures, namely, $x_A = (x_{A_1}, \dots, x_{A_n})$. By averaging over n , we get the quantity $\bar{x}_A$, which is an estimate of the true table weight η . A systematic error occurs when the current estimate $\bar{x}_A$ differs from η by a systematic positive or negative quantity τ (i.e., $\eta = \bar{x}_A + \tau$). It has the property that $\eta \neq \bar{x}_A$ even though we keep new measurement samples. As such, systematic errors affect the measurement process by introducing a constant bias over measurements. On the contrary, a random error does not introduce any bias in the measurement process: If we repeatedly measure the table weight then the estimate $\bar{x}_A$ will approximate the true quantity η ($\bar{x}_A = \eta$ as a limit case). Then, what the random error introduces in the measurement process is a stochastic fluctuation of the measurements $x_{A_1}, \dots, x_{A_n}$ around η . These fluctuations are predictable and behave according to a predefined probabilistic model, for instance, the Gaussian model (also known as *white noise*). In this sense, while the systematic error may be removed by identifying

the source causing biases, random error cannot be removed because it is inherent in the measurement process.

Sampling Error

Sampling error is the difference between the true quantity η and its estimate $\bar{x}_A$ that is computed given a sample of measurements. It is due to the fact that we use samples in order to estimate η , the unknown measure, and we are going to quantify. With a slightly different terminology, in statistics true but unknown quantities are called parameters, and samples of measurements are drawn from a target population. Then, the sampling error is simply the approximation we get by estimating the population parameters through statistical samples.

Errors in Statistical Models

Random errors are the cornerstone of statistical modeling. In general, a statistical model is of the form $Y = f(X) + \epsilon$, where Y is the response variable (also known as *outcome*), X is the set of predictors (or *covariates*), and f is a function that deterministically links X to Y . In this context, ϵ is the random error term, which makes the model different from a standard deterministic or mathematical model. The simplest case of a statistical model is the linear one, in which model predictions are represented as a straight line (or a plane) as follows:

$$\hat{Y} = \hat{\alpha} + \hat{\beta}X \quad (1)$$

In this formulation, $\hat{Y}$ contains the predictions of the model (i.e., the expected values), X is the matrix containing the variable currently predicting the outcome, whereas $\hat{\alpha}$ and $\hat{\beta}$ are the estimated (i.e., based on available data) parameters of the model, namely, the intercept and slopes, respectively. As a result of the presence of the random error, the relationship between observed and predicted data is corrupted by random fluctuations:

$$Y = (\hat{Y} + \epsilon) = \hat{\alpha} + \hat{\beta}X + \epsilon \quad (2)$$

In order to keep the model as simple as possible, two basic assumptions follow: (i) the error ϵ is Normally distributed around zero with constant variance, and (ii) the variance does not change as a function of the predictors X . These assumptions are formally defined with the well-known probabilistic notation $\epsilon \sim \mathcal{N}(0, \sigma^2)$. As an example, consider a data-set of $n = 260$ high school students. For each student, two characteristics are available at the same time: the time (in hours) spent to do homework (X), and the final score in a mathematical test (Y). Figure 1a shows the observed outcome Y as a function of the predictor X . It seems quite clear that test scores increase as the time spent to do homework also increases.

The black line is the estimated regression line with the following equation: $Y = 45.3 + 3.7X$. In the current example, the model predicts (on average) that a student who spends $X = 0$ (hours) to do homework will have a math score equal to $\hat{Y} = 45.3$. By inspecting the figure, it can be noticed that actual math scores ranges from 27.5 to 60.7. For example, the first student with $X = 0$ (hours) shows a math score equals to

$Y = 44.3$ with a difference of $Y - \hat{Y} = -1.0$ scores from the model predictions. This is due to the prediction error of the model.

As a consequence, the differences between the current math scores (Y) and the predictions ($\hat{Y}$) can be computed via Eq. (2). Figure 1b depicts the distribution of the prediction errors (also known as *model residuals*). As expected, residuals are close to zero (on average) and range between -25.5 (minimum) and 31 (maximum). The spread around zero it is due to the error component ϵ , which is the random noise term. Note that if the model was able to predict math scores perfectly (i.e., with no differences between observed and predicted values), the errors would be zero and the model fit would consequently be perfect. As a by-product, an index used to evaluate model fit is the well-known R^2 (R-squared), which is computed as the ratio between error variability and total observed variability. It is formally defined as follows:

$$R^2 = 1 - \frac{\text{Error variability}}{\text{Total variability}} \quad (3)$$

In case of perfect fit, all errors would be pushed toward zero, error variability would

Error, Fig. 1 Hours spend for homework and mathematical test scores in a sample of $n = 260$ high school students. (a) The straight black line represents the linear model predictions whereas the gray area represents the uncertainty

related to the previsions. Data were jittered on the x-axis to enhance legibility. (b) Distribution of the errors as computed by the difference between observed and predicted math scores

Error, Fig. 2 Example of multilevel structure. (a) The black line is the regression line estimated on all data ($n = 260$); the red line is the regression line estimated on

students in a specific class (black points, $n = 23$). (b) Colored lines and points referred to the different 12 classes

also tend to zero, and the R^2 index would be equal to one.

As many data types show a hierarchical or clustered structure (Gelman and Hill 2007; Pinheiro and Bates 2000), it is possible to further decompose the error term into two subcomponents. In the current example, students are naturally clustered into 12 different classes, which are in turn clustered into 4 schools. In this case, estimating model parameters assuming that observations are independent could lead to biased estimates.

Figure 2a shows the math scores of a subset of students in a selected class (black dots). The red line is the regression line which has been estimated based on these observations. As we can notice, the current regression line is quite different from the previous one (in black color): because it has been estimated on a few number of observations, its slope is strongly influenced by two observations showing longer working time. For instance, consider the student associated to $X = 5$ (hours) and $Y = 59.4$ (math score). In Fig. 2a, this observation has been highlighted with a black circle. This student math performance is 4.2 scores below the black line – which is the expected value from the pooled regression model – and 5.5 scores above the red line – which is the expected value with respect to his

class. Then, two sources of errors arise in terms of difference between observed and predicted scores: The first represent the difference by the pooled model, and the second represent differences for each specific group/class. As a result, different regression lines can be estimated for each group in the sample. Figure 2b shows the linear models for each of the 12 classes in the sample. By means of this example, we have described a well-known statistical tool – i.e., multilevel modeling – used in many disciplines, including those interested in studying individual differences. Unlike standard linear regression models, multilevel models aim at finding a compromise between the pooled model – which ignores the nested structure of the data – and the non-pooled model – which instead considers each group separately in the sample. This gives rise to two subcomponents of the general error ϵ , namely, $\epsilon_{\text{overall}}$ which is the overall sample uncertainty and ϵ_{groups} , the component referring to the subject-specific uncertainty.

Conclusion

Over the past 20 years, the development of computing algorithms and the growth of computational power have made possible what was

considered impossible in statistics. In particular, nowadays it is possible to evaluate statistical models characterized by very complex error structures (e.g., mixed-effects models), that are also increasingly close to the complexity of real phenomena. These models, which are difficult to express analytically, can be estimated through resampling and simulation methods that require the use of high performance computers. In these models, complex error structures can be taken into account and different scenarios can be evaluated on the basis of several theoretical hypotheses. From this perspective, the analysis of errors allows to evaluate the variability of observed data and the associated uncertainty of model predictions in depth. Finally, the analysis of errors can suggest the possible presence of variables or relationships between variables not previously taken into account, thus paving the way for new theoretical hypotheses.

Ethics of Possibility

Abstract

We can think about the relationship between ethics and the possible in two ways. First, in order to be ethical, we need to be able to imagine what is possible, so that we can

deliberate about what we should do. Second, in order to improve ourselves, we need to be able to imagine ourselves and even our world differently, and to see that alternative as a real possibility so that we can deliberate about how to make it a reality. The possible delineates the moral realm in the sense that we assign responsibility and blame according to what is possible, and as we compare what is necessary to what is merely possible when making ethical decisions. As a tool for ethical reasoning, the possible can be seen as either a catalyst or an obstacle. In one sense, the possible is the input for our moral imagination, but possibilities also act as cautionary tales, for instance, in respect to developing new technologies with uncertain potential. What is possible, on the other hand, can hinder our ability to act ethically, when we find ourselves overwhelmed or lost in possibility itself.

Introduction

Ethics is a matter of how we behave with and toward one another, and the study of ethics is an examination of what counts as good or bad behavior. It is more than an examination of what is true about our behavior, it is also a study of the norms and values that *should* guide our behavior. Possibility is an essential part of ethics. This is not only because “what is possible” is a normative question – that is, a question that requires values to answer fully – but also our very ability to ask that question is what allows us to be ethical beings in the first place.

We can think about the relationship between ethics and the possible in two ways. First, in order to be ethical, we need to be able to imagine what is possible, so that we can deliberate about what we should do. For instance, if we want to decide what is the right thing to do, we often consider the probable consequences of our proposed actions:

Even if probability is the tool by which we compare alternatives, we first must consider what the possible outcomes of our actions are before we can think about their likelihood. Second, in order to improve ourselves, we need to be able to imagine ourselves and even our world differently, and to see that alternative as a real possibility so that we can deliberate about how to make it a reality. We believe that a good life is possible, and that is why we make the good life our pursuit.

There are also several different ways that the possible intersects with ethics in the history of philosophy as well as in more recent work. First, there is the question of what is actually possible: In ethics, we argue that we should not demand things of people that they cannot actually do; every “ought,” that is, implies a “can.” Another way to think of this is that an obligation must entail a possibility. But what kind of possibility must it entail? In the sense of a *logical* possibility, “what is possible” is what could happen, or rather what would not be prevented from happening. This is in opposition to the actual, what is happening, or the probable, what is likely to happen. The possible can be logically possible even if it never actually comes into being. Aristotle makes this ancient Greek idea of the possible more concrete with his idea of potentiality: The essence of a creature or a thing determines what is necessary about it, or what it has potentiality for, whereas the accidental denotes properties that are not necessary in that essential way. I have necessary features as a human, being rational and having a certain kind of body, but whether that body is tall or short is an accidental property; accidents can occur or not without altering the essence of the creature or thing. So the accidental is the merely possible, in this account, but it remains pragmatically relevant in the sense that such contingencies must be accounted for in practical reasoning. Ethical action, for instance, according to Aristotelian virtue theory, emerges from the ability of a person to reason successfully about the possible actions they can take in a particular situation, and to choose the action that a virtuous person would choose.

The possible has also been considered necessary for moral action in other ways. Harry

Frankfurt (1969) has, for instance, labeled a key criterion for assigning moral responsibility, “the principle of alternate possibilities.” Moral responsibility, according to this principle, can only be assigned to those people who “could have done otherwise” – that is, to those who willingly chose this possible action or future over other (known or obvious) possibilities, and whose actions were not determined by coercion or other constraints. Frankfurt only labeled the category in order to critique it; however, and as David Robb (2020) points out in the Stanford Encyclopedia of Philosophy entry on this topic, logical possibility is not sufficient for this criterion: In cases where it is theoretically or logically possible to do something, but not actually possible (such as a drug addict being able to simply drop their habit), then moral responsibility is again in question.

As a tool for ethical reasoning, the possible can be seen as either a catalyst or an obstacle. Utopias have long been part of ethical reasoning, set as a future possibility, and also an ideal for society to strive for, with famous examples from Plato through Moore. Similarly, many see science fiction as a resource for ethical thinking, introducing and working through possible future scenarios toward which we can strive or about which we should be cautious (e.g., De Cruz et al. 2021). In one sense, the possible is the input for our moral imagination; as Matthew Brown has recently argued (2020), moral imagination is required for much of our ethical reasoning, insofar as we must imagine how others might feel or respond, we must imagine the possible impact of our decisions and behavior, and we need to imagine possible ends and ideals toward which we can progress. Lorenzo Magnani explores the relationship between moral reasoning and abduction, the kind of reasoning we employ when considering possible explanations – moral reasoning in this sense “can be viewed as a form of ‘possible worlds’ anticipation” (2006, p.206). In the realm of science and technology, the possible not only drives creative innovations, but also gives content to our ethical reasoning. Philip Brey (2012), for example, has proposed that an “anticipatory ethics” is required for addressing the possible impact of emerging technologies; where we do

not yet know how things will go, we must imagine what will possibly happen in order to take precautions and shape our designs in ways that avoid undesirable outcomes and encourage desirable ones. Possibilities that ethicists should focus on mapping, suggests Brey, are those that are potentially harmful, should they occur; similarly, the standard use of the “precautionary principle” in ethical deliberations demands that the burden of proof is on those who would say that harmful consequences of a new technology or innovation are improbable – a company that wants to do something new, that is, must first take precautions to think through possible harms and act to reduce the probability of bad things happening as a consequence.

The possible futures that new technologies introduce into our world frequently generate discussion and debate in ethics, about whether we ought to pursue or prevent such possibilities when we have the choice. With the advent of genetic modification, for example, discussions about what possibilities there are for humans, individually or as a species, have been brought to the fore. Julian Savulescu has famously argued that because it is now possible to alter our genetic future for the better, we have a moral duty to do so: We ought to improve our future generations as we can, and when we have the technology to do so, we ought to use it. This “transhumanist” perspective suggests that part of our ethical duty is to intentionally and consciously ensure that the next generation has the “best life possible,” which may entail changing the very nature of humans through technology (e.g., Savulescu and Bostrom 2009). This approach is in sharp contrast with another well-known ethical debate about “possible humans,” taken up most explicitly by David Banatar’s (2006) argument that existing at all, given the possible benefits and possible harms to any given individual who lives, is on balance always a harm; rather, we are better never to have been at all. The underlying philosophical idea here is that any possible human is likely to live a terrible life, and since we have an ethical duty not to bring harmful possible futures into being where we can, we have a duty not to procreate new

possible humans either (see Parker 2007 for a review & critique of key positions in this debate).

Possibility, therefore, highlights two forms of moral responsibility, active and passive: Where we can act toward better possible futures, we ought to; when we willfully choose harmful possibilities over better ones, we are blameworthy in retrospect. These types of moral responsibility, however, presume that freedom of choice about possibilities and even the limits of our moral imagination are unrestrained. This is not the case, however, in many situations and for many people: Oppression, as feminist theory has pointed out, can limit what we can imagine to be possible in ways that have ethical significance. Maria Pia Lara (2008), for example, argues that the women’s movement was transformative because it envisioned as possible and then made real new forms of democracy, justice, and the good life. Without such transformative change, it was not possible for women to live the good life they imagined; the link between ethics, possibility, and reality becomes clearest in transformative contexts.

Indeed, denying this link can also have ethical significance, as Søren Kierkegaard and, more recently, Sara Ahmed have addressed with their philosophical approaches. Kierkegaard, in his work *Either/Or*, delineates the choice we have between seeing the possible through an aesthetic or ethical lens (see, eg., McDonald 2021). The misdirected aesthete dwells on the possible as an alternative to the actual; they focus on what has been and what could be, if only things were different than they are. This is misdirected because it leads them into the realm of infinite possibility and thereby inaction (or, in the extreme case, deep irony, where the actual is fully reduced to the merely possibly otherwise, and thereby dismissed). An ethical attitude toward the possible, on the other hand, sees the possible as inspirational and guiding, marked by reflection and self-knowledge rather than despair.

Similarly, Ahmed points to how the recognition of possibility can block our ability to be happy. In the conclusion to her book *The Promise of Happiness*, she argues that because it is

always a possibility that one might be unhappy, in order to be happy it seems one must exclude not only unhappiness but also possibility itself. As Kierkegaard noted, the realm of possibility is a realm in which all things are equal: “Possibility means grasping terror as well as joy” (Ahmed 2010, p. 219). Following Jean-Luc Nancy, Ahmed then suggests we might take “happenstance” as the appropriate approach: Where we must accept and also choose between good and bad possibilities at every turn, happiness is one possibility among others. Such an openness to possibility, in turn, provides the conditions for ethical encounters (p. 220). Embracing possibility as such, without getting lost in its infinitude and thereby failing to act on any possibility, is the key to ethics, according to such accounts.

The idea of an ethics of possibility has been explored by a few. Arjun Appadurai (2013), in a series of essays “on the global condition,” proposed a distinction between ethics of probability, which take management and measurement as their tools for moral decision-making, and the *ethics of possibility*. The latter, Appadurai suggests, includes “those ways of thinking, feeling, and acting that increase the horizons of hope, that expand the field of the imagination, that produce greater equity in what I have called the capacity to aspire, and that widen the field of informed, creative, and critical citizenship” (p. 295). Seana Moran picks up a similar theme in her 2014 chapter, “An Ethics of Possibility,” discussing how creativity can ground ethics. Such an ethics would be “built on opportunities,” in contrast to traditional rule-based ethical frameworks that list principles and virtues as guides toward ideals. Such an ethics would provide “a valuing of what is beyond the known and accepted, a humility about what we already understand against the vastness of what we may not, and a courage to pursue unknowns” (p. 288); Moran suggests that creativity itself may be a moral obligation, and that creativity and ethics are iterative and ought to be integrated. Mikhail Epstein (2019) promotes a ‘possibilist mode of thinking’ with his philosophical investigation into the modalities of the possible, with the aim to encourage transformative

thinking and paradigm shifts in culture and thought.

Thus, the possible not only delimits our ethical actions and our moral responsibility, but is also necessary fodder for moral imagination, empathy, and utopian and other forward-thinking ethics. It can hinder our actions if we find ourselves overwhelmed by it, and allow ourselves to dwell in the aesthetic or the ironic or the simply happy instead. When we adopt ethical attitudes that embrace the possible, however, we not only do so by way of allowing ourselves to be uncomfortable in a place where both good and bad possibilities reside, but we also thereby open ourselves up beyond the universal principles of traditional rule-based ethics, or move beyond descriptive ethics about what is happening now to think about possible (potentially transformative) futures, those we should strive for as well as those we should strive to avert.

Existentialism · Jean-Paul Sartre · Philosophy · Phenomenology · Humanism

Definition

Jean-Paul Sartre was a French philosopher, writer, political activist, and literary critic. He was one of the most renowned intellectuals of the twentieth century. He is considered as the main representative of French existentialism (also known as French existential phenomenology). His capital philosophical work, *Being and Nothingness* (1943), turned into an unexpected popular success. By the end of World War II, existentialism had become an intellectual fashion, like surrealism after World War I.

Consistent with his atheism, Sartre relegates the essence. If there is no God, no Creator, then, there is no human nature, no previous definition of man, no a priori. Man is thrown into existence being nothing, and Sartre tries to extract all the

possible conclusions from this radical starting point. According to him, man is nothing but what he makes of himself. Having no essence, he is always confronted to the choice of what he wills to be. Then, “man is condemned to be free”, but he is also responsible for what he becomes.

Sartrean consciousness, as a nothingness deprived of being, is the ontological foundation of freedom. That is why the French philosopher opposed any kind of determinism, particularly that of Freudian psychoanalysis, but also the one of traditional psychologies, Marxist philosophies, etc. On the other hand, the non-coincidence of consciousness with itself, and, at the same time, its separation from reality, implied “the possibility of the possible”. In other words, Sartre’s conception of the possible is grounded on the same nothingness that is synonym to freedom.

Introduction

Jean-Paul Charles Aymard Sartre (1905–1980), better known as Jean-Paul Sartre, was a French philosopher, writer, political activist, and literary critic. He was one of the most renowned intellectuals of the twentieth century. Along with his partner, the writer and philosopher Simone de Beauvoir, he is considered as the main representative of French existentialism (also known as French existential phenomenology). In his philosophical essays and novels (such as *Being and Nothingness*, 1943, and *Nausea*, 1938), Sartre recuperated an ancient intellectual tradition stressing the absurdity of existence, the meaninglessness of life, and as a consequence, the original helplessness of mankind. His predecessors can be traced back to Fyodor Dostoevsky and Friedrich Nietzsche, but also to Søren Kierkegaard and Martin Heidegger.

In his first philosophical steps, in the 1930s, Sartre was guided by Henri Bergson and Edmund Husserl, who emphasized the importance of consciousness as the true source of human experience. Husserl’s phenomenology, which implied a “return to things” as they were shown by “lived experience”—as they “appeared” to consciousness—was for Sartre a springboard. However, at that

early stage, he already had a different point of view about the ego, which he did not consider “transcendental,” but a mere illusory object (Sartre 1937). According to the young French philosopher, we identify ourselves with an ego, we think that we are that object – a personalized, biographical self – only to deny that we are nothing but an impersonal consciousness. In fact, for Sartre, from the very beginning, the practical function of the ego was to hide the active character of the consciousness we are, of that creative “nothingness” that reveals its own objects, including the ego that we usually take, mistakenly, as the master of consciousness – if there was such a thing as a center of consciousness, for Sartre it would be closer to body than to the ego. This split between consciousness and ego, where the latter plays a secondary and delusional role, would later be developed by Jacques Lacan in his famous “looking-glass phase” (see Lacan 1964/1981). At that moment, both thinkers were profoundly influenced by Hegel’s dialectical and intersubjective theories.

Existentialism as a Form of Humanism

In the 1940s, in the footsteps of Heidegger, Sartre’s phenomenology would become an existential one. His capital philosophical work, *Being and Nothingness* (Sartre 1943/1958), turned into an unexpected success. By the end of World War II, existentialism had already become a fashion in the intellectual circles, like surrealism after World War I. In spite of its growing popularity, at the time, existentialism was criticized by Catholics and Communists alike, the former claiming it was a materialist and atheist doctrine, and the latter protesting that it was too subjective. Phrases taken out of context, like “Hell is other people” or “Man is a useless passion,” had also provoked lots of controversy in the general public. In a postwar period – a moment of hope and reconstruction – existentialism was seen as a pessimistic doctrine proclaiming despair and nihilism (Elkaïm-Sartre 1996/2007).

In this context, it is understandable that, in 1945, Sartre took the effort to introduce

existentialism under a different light. He did so in a conference he gave a few days before the launching of a journal that would be legendary: *Les Temps Modernes* (which he founded with his partner, Simone de Beauvoir, and their common friend, the philosopher Maurice Merleau-Ponty). The very title of the conference, *Existentialism is a humanism* (Sartre 1946/2007), gives an idea of its content. Sartre did his best to show how his philosophy, however dark it could seem, had a lot to do with human freedom and with the future of mankind:

Atheistic existentialism, which I represent, is more consistent. It states that if God does not exist, there is at least one being in whom existence precedes essence—a being whose existence comes before its essence, a being who exists before he can be defined by any concept of it. That being is man, or, as Heidegger put it, the human reality. What do we mean here by ‘existence precedes essence’? We mean that man first exists: he materializes in the world, encounters himself, and only afterward defines himself. If man as existentialists conceive of him cannot be defined, it is because to begin with he is nothing. He will not be anything until later, and then he will be what he makes of himself. Thus, there is no human nature since there is no God to conceive of it. Man is not only that which he conceives himself to be, but that which he wills himself to be, and since he conceives of himself only after he exists, just as he wills himself to be after being thrown into existence, man is nothing other than what he makes of himself. This is the first principle of existentialism (Sartre 1946/2007, p. 22).

Against an ancient philosophical tradition, from Plato to Husserl, Sartre relegates the essence. If there is no God, no Creator, no “superlative artisan,” then, there is no such a thing as a human nature, either. No universal concept of man, no previous definition, no a priori. Man is thrown into existence being nothing. And Sartre tries to extract all the possible conclusions from this radical starting point. According to him:

- Man is nothing but what he makes of himself.
- ‘Man is condemned to be free’.
- He is responsible for what he becomes (or what he chooses to be in line with his acts).
- There are no excuses, no alibis.
- To take refuge behind passions or behind deterministic theories equals to ‘bad faith’.

- Anguish, abandonment and despair derive from the responsibility that comes with freedom.
- Existential anguish leads to action and commitment, not to immobility or contemplation.
- Man can only be defined in relation to his actions and commitments.

Considering these principles, why would existentialism be a sort of humanism? “This is humanism [. . .] because we show that it is not by turning inward, but by constantly seeking a goal outside of himself in the form of liberation, or of some special achievement, that man will realize himself as truly human” (Sartre 2007, p. 53). In other words, if existentialism was related to humanism, it was through the promise of the realization of man’s possibilities. For Heidegger, however, Sartrean humanism stayed on a metaphysic and subjective level. Giving precedence to existence over essence, it forgot the fundamental problem: “the truth of Being” (Heidegger 1946/1999).

The Ontology of Freedom

The ontology of Sartre’s existentialism was developed extensively in *Being and Nothingness* (1943/1957). Nevertheless, his conception of being was not equal to Heidegger’s. In fact, this “essay on ontological phenomenology” was meant as a study of the structures of experience and consciousness, in order to understand the way reality manifests itself. In the Husserlian tradition, objects “appear” to consciousness, they “reveal” themselves. And a phenomenological analysis tries to carefully describe how these appearances are produced, for they show the very structure of the human world. Strictly speaking, for Sartre, there was only one true form of being: the being of matter, of physical objects, as opposed to human consciousness, which was not “true being,” but nothingness: the negation of being. As a presence, as the activity of “being aware” of objects, consciousness intends objects, but it is never an object. Not even when it tries to reflect about itself. There is always a distance, a

noncoincidence between consciousness and the objects it reveals and negates, differentiating itself from them.

Following Hegel, for Sartre, the real is dialectical, and negativity plays a key role in humanizing reality. As king Midas did with gold, Sartre’s consciousness turns to nonbeing everything it touches. Actually, human consciousness is the only way of “nihilating” (a Sartrean neologism), of introducing a lack, a bit of nothingness in the realm of being, where nothing lacks. If being is defined by its completeness, its self-sufficiency, and its identity (it is what it is), nothingness is sheer negativity: pure lack and difference introduced by consciousness (that is what it is not). Unlike Hegel’s, though, in Sartre’s world, there is no *Aufhebung*, no transcendence of the conflict between being and nothingness, whose relationship always remains problematic and unresolved (Descombes 1979). The fact that Sartre adopted Hegelian vocabulary to designate these two ontological regions does not simplify the affair. The being-in-itself (*être-en-soi*) of the material objects and the being-for-itself (*être-pour-soi*) of consciousness can never reach an impossible synthesis (being-in-itself-for-itself) that the French philosopher compares with the “desire to be God.”

Sartrean consciousness, at last, even deprived of being, of which it always depends, as a nothingness, is the ontological foundation of freedom. If there is no human nature, no a priori definition of man, every man has to begin by making an initial decision related to being. He has to give himself a fundamental project concerning the others, the world, and his own body. He has to find his own way “to-be-in-the-world.” The possibility of not choosing does not exist. It carries all the weight of responsibility. Hence, man “is condemned to be free” (Sartre 1943/1957, p. 129). Yet, if Sartrean freedom is another name for damnation, it is not pure openness. It carries all weight of responsibility in a desperate attempt to be. It has not the lightness of a boundless free will. “The for-itself chooses because it is lack; freedom is really synonymous with lack. Freedom is the concrete mode of being of the lack of being” (Sartre 1943/1957, p. 565).

This radical conception of freedom – criticized by friends and foes – made the French philosopher oppose any kind of determinism, particularly that of Freudian psychoanalysis, but also the one of traditional psychologies, Marxist philosophies, etc. For Sartre, any given behavior needs to be understood in the light of the “original choice” and not mechanically explained. Human conducts become meaningful regarding the future, not the past. There is no linear unconscious causality but the inscription of an action in a totality, in “a project of itself toward a possible” (Sartre 1943/1957, p. 460). This kind of comprehension (*verstehen*) is the one Sartre proposed for what he called “existential psychoanalysis,” as opposed to “empirical psychoanalysis.” “This psychoanalysis has not yet found its Freud. [. . .]. But it matters little to us whether it now exists; the important thing is that it is possible” (Sartre 1943/1957, p. 575).

Existentialism as a Philosophy of the Possible

The “modal vocabulary” – not to say a “modal logic” – had great popularity in the French thought of the twentieth century. Thus, it was not rare to find modalities – such as “the necessary” and “the contingent,” “the possible” and “the impossible” – as categories serving to organize different theories and to formulate definitions. For example, for Bergson (1934), the real was the possible, while for Lacan, on the contrary, the real was the impossible – the impossible to bare, the impossible to symbolize, and so forth. For Derrida (2007), at his turn, the real could be defined as “an impossible possibility.” In this context, in the 1940s, Sartre used to combine those modalities, to the point that Sève (1996) even attributed him a “modal ontology.” “Being-in-itself is never either possible or impossible. It is [. . .]. Consciousness absolutely cannot derive being from anything, either from another being, or from a possibility, or from a necessary law” (Sartre 1943/1958, p. lxvi); “we could define the body as the contingent form which is assumed by the necessity of my contingency” (Op. cit., p. 309).

Beyond the tongue twisters, among those modal terms, for Sartre, “the possible” was the

crucial one, so he dedicated it a seven-page paragraph of *Being and Nothingness*, although the category is omnipresent in the book, receiving multiple definitions: “The possible is an absence constitutive of consciousness in so far as consciousness itself makes itself” (Op. cit., p. 101). “The possible is the something which the For-itself lacks in order to be itself. [. . .] The possible does not exist as a pure representation, not even as a denied one, but as a real lack of being which, qua lack, is beyond being. It has the being of a lack and as lack, it lacks being. The Possible is not, the possible is possibilized to the exact degree that the For-itself makes itself be; the possible determines in schematic outline a location in the nothingness in which the For-itself is beyond itself” (Op. cit., p. 102). In every case, the possible implies a noncoincidence of consciousness with itself, a distance with what I am and, at the same time, a separation from reality. In other words, the possible is grounded on the same nothingness that is synonym to freedom. It is a fundamental concept that can be used to define the for-itself, the situation, and temporality, but death and desire as well. It is such an important notion that it gives the book its “tonicity” (Sève 1996).

For Bergson (1934), the possible is a self-deception. For him, there are free acts that once they are carried out, retrospectively, give us the illusion that they were a possibility. For Sartre, in turn, possibility is a property of an existing human reality, which is not a quality of things nor a purely subjective faculty, like thought or imagination. Against Aristotle, Leibniz, and Spinoza, Sartre stated that a representation may be true or false, but could never become possible. For example, “in order for the rain to be possible, there must be clouds in the sky” (Op. cit., p. 98). However, the rain is not in the clouds as a “potentiality” – as Aristotle would say – since the in-itself is only what it is. In its plenitude of being, it is not – or it does not have – potentialities. The clouds are vapor, not potential rain. “These clouds can change into rain only if I surpass them towards the rain” (Op. cit., p. 98). It is not the ego that is capable of this surpassing, but the for-itself that can transcend its situation, “possibilizing” the

rain. Transcendence, in this case, implies otherness, not just nothingness (Epstein 2019).

In the end, there is a hierarchy of possibilities, ranging from the less to the more personal. In fact, my ultimate possibilities are, on the one hand, the original project, my fundamental choice, and, on the other hand, death, “the possibility that there are for me no longer any possibilities” (Sartre 1943/1958, p. 547). The initial project that I am gives meaning to all my other possibilities. It is the whole structure in relation to which all my actions make sense. For example, examining the cases of thirst or sexual desire, Sartre comes to the conclusion that satisfaction is always somehow disappointing, not because there is no pleasure, but because of “the evanescence of the coincidence with self” (Op. cit., p. 102). “For the for-itself attained by the realization of the Possible will make itself be as for-itself—that is, with another horizon of possibilities” (Op. cit., p. 101). In this context, desire appears like a void that not necessarily calls to be filled. Sometimes, unrealized possibilities are more intense than real experience (Epstein 2019). “In itself indeed desire is an emptiness. But no non-reflective project aims simply at suppressing this void. Desire by itself tends to perpetuate itself; man clings ferociously to his desires” (Op. cit., p. 101).

The fundamental desire, though, remains that of an impossible coincidence between the for-itself and the in-itself. “This is why the possible is projected in general as what the for-itself lacks in order to become in-itself-for-itself” (Op. cit., p. 566). A philosophy of the possible consistent with this Sartrean conception of desire should not take freedom as the maximal realization of possibilities, which would amount to their elimination, but should rather aim at a “peaceful coexistence” with the incompleteness inherent to consciousness.

Summary

In the 1940s, Jean-Paul Sartre coined a new philosophy, French existentialism, which underlined the fragility of being. His conception of human consciousness as a nothingness, far from diminishing the importance of man, laid the

grounds for a kind of humanism that placed freedom in the center of human reality. For man, according to existential philosophy, once he is “thrown into existence”, the fundamental choice, the original project, is an answer to the question of being. Against all forms of determinism – but also against common sense, for Sartre, that answer is always more related to the future, to the dimension of the possible, than to a past that has already been.

Extended Mind

Victor Loughlin

Centre for Philosophical Psychology, Department of Philosophy, University of Antwerp, Antwerp, Belgium

Abstract

Extended Mind is usually understood to be a claim about cognitive extension, that is, it is usually understood to be the claim that the boundaries of the mind can occasionally extend to include objects in the environment. This chapter will argue that understanding Extended Mind in this way helps zero in on how this claim should be defended. For example, Clark and Chalmers' (1998) Parity Principle (PP) states that if bodily external objects play roles functionally equivalent to processes inside the head, and those in-the-head processes are regarded as cognitive, then those bodily external objects should be regarded as playing cognitive roles as well. If Clark and Chalmers are correct, then PP can be used to defend Extended Mind. As this chapter will show, the pivotal role PP plays becomes apparent when we consider what happens when PP is either minimized, as is the case with second wave Extended Mind, or removed altogether, as is the case with third wave Extended Mind, since it can be doubted that either of these two readings are in fact readings of Extended Mind. Third wave, in particular, may need to be understood in entirely different terms. This suggests that if Extended Mind is understood to be a claim about cognitive extension, then PP should be regarded as key to defending that claim.

Introduction

Take a look at the objects around you. Could those objects be part of your mind? Indeed, where exactly does your mind end and the rest of the world begin? In recent decades, philosophers of mind and cognitive scientists have begun to challenge the intuition that our minds are confined to the insides of our heads.

Consider someone's use of his or her Smartphone. This person may constantly use their phone, easily access the information stored on their phone, and sometimes even automatically endorse this information, like when such information is about the phone numbers of their friends. It might be thought that this Smartphone is just a tool like any other, employed by this person to complete a given task. However, some philosophers of mind and cognitive scientists argue that given the sorts of "glue and trust" conditions just mentioned – constant use, easy access, and automatic endorsement – then a person's Smartphone could be as much a part of this person's mind as anything inside their head (Chalmers 2008). If so, then the Smartphone can, under these particular circumstances, extend the mind of this person. This, so it is claimed, is an example of what is called Extended Mind or EM for short (Clark and Chalmers 1998; Menary 2010a).

As this example illustrates, EM is usually understood to be a claim about cognitive extension, that is, it is usually understood to be the claim that the boundaries of the mind can occasionally extend to include objects in the environment. One reason to think that EM should be understood in this way is that it helps demarcate it from its close conceptual rival, the Hypothesis of Embedded Mind (HEMC) (Loughlin 2018a).

For example, proponents of HEMC, e.g., Adams and Aizawa (2001, 2008) and Rupert

(2004), think that, while objects in your environment, like Smartphones, may be crucial to the completion of certain cognitive tasks, it does not follow that such objects thereby extend the boundaries of your mind. Indeed, claiming that such objects do extend the boundaries of the mind, so say proponents of HEMC, raises a host of metaphysical issues that are best avoided, such as demonstrating that objects in the environment can play a constitutive and not merely causal role in the formation of cognitive processes. If these proponents are correct, then while some objects may help one cognize, it doesn't follow that minds also extend to include such objects. Hence, framing EM as a claim about cognitive extension matters. This is because it clarifies the ways in which EM and HEMC are in fact separate and distinct claims.

Importantly, as this chapter will show, understanding EM as a claim about cognitive extension, in the manner previously formulated, helps zero in on how this claim should be defended. This will be the central theme of this chapter, which can be illustrated in the following way.

Clark and Chalmers (1998) offer what still remains the canonical formulation of EM, according to which claims about cognitive extension are made on the basis of what is called the Parity Principle (PP). PP states that if bodily external objects play roles functionally equivalent to processes inside the head, and those in-the-head processes are regarded as cognitive, then those bodily external objects should be regarded as playing cognitive roles as well. If Clark and Chalmers are correct, then PP can be used to defend EM.

By contrast, Sutton (2010) develops an alternative reading of EM, which he calls "second wave." Following second wave, objects need not have parity with inner cognitive processing but rather can complement and even transform such processing. Second wave thus looks to minimize the role of PP in making the case for EM. However, this leaves it unclear that second wave actually is a reading of EM. Indeed, Sutton seems to concede as much when he acknowledges that second wave might be better understood as a

methodological claim rather than a claim about cognitive extension.

On the other hand, Sutton (2010) also suggests that there could be a possible third wave reading of EM. Kirchhoff and Kiverstein (2018) develop this suggestion in detail, claiming that cognitive processes are dynamically unfolding activities realized by the practices in which agents are enculturated. Third wave thus removes any commitment to PP. Yet this raises further questions as to what exactly extends. One option then is to read third wave, not as a version of EM but rather as an enactivist proposal, although this new reading encounters a problem of its own. Another option is to employ Glaveanu's (2018) notion of the possible. However, doing so reveals the extent to which third wave radically departs from both EM and enactivism.

These considerations highlight the pivotal role PP plays in making the case for EM. For as discussion of second wave and third wave readings demonstrate, once PP is minimized or removed altogether, then it is no longer clear that we are still talking about EM. Hence, if EM is understood to be a claim about cognitive extension, then PP should be regarded as key to defending that claim.

The layout of this chapter is as follows. Section "[Extended Mind](#)" outlines Clark and Chalmers' original reading of EM. Section "[Second Wave Extended Mind](#)" discusses Sutton's proposed second wave reading of EM. Section "[Third Wave Extended Mind](#)" turns to a possible third wave reading, with some reference to Kirchhoff and Kiverstein.

Extended Mind

Although EM has many precursors in the philosophical literature, e.g., Dewey (1916), it was nonetheless first explicitly outlined and defended in a seminal paper by the philosophers Andy Clark and David Chalmers (1998).

In that paper, Clark and Chalmers introduce an idea that has since come to play a defining role in the debate over EM. They state:

If, as we confront some task, a part of the world functions as a process which, were it done in the head, we would have no hesitation in recognizing as part of the cognitive process, then that part of the world *is* (so we claim) part of the cognitive process. (ibid., p. 8 emphasis in original)

For example, consider the game Tetris. As most people know, players of this game must quickly alter the shapes of falling Tetrominoes so that these objects can form a solid line at the bottom of a screen. Players can do this in a number of ways. They can, for instance, mentally calculate how these Tetrominoes should be altered before making the necessary adjustments on the screen. Or they can instead use a physical rotation device to make those adjustments.

According to Clark and Chalmers, manipulating the shape of the Tetrominoes using a rotation device is logically on a par with manipulating the shape of the Tetrominoes inside your head. This is because using such a device forms a process such that were this process done in the head we would regard it as part of a cognitive process. Given this equivalency between use of the device and in-the-head processing, then we should regard the use of this device as part of the player's cognitive processes. Clark and Chalmers employ this example to conclude that, "[c]ognitive processes ain't (all) in the head!" (ibid.).

In subsequent debates over EM, Clark and Chalmers' idea has come to be called the Parity Principle (PP). PP has been challenged in numerous ways (Menary 2010a). However, for the purposes of this chapter, it will be assumed that PP succeeds in making the case for EM. Given this assumption, two aspects of PP can be highlighted.

First, PP is meant to act as a "veil of metabolic ignorance" or an insistence on "equality of opportunity: avoiding a rush to judgment based on spatial location alone" (Clark 2008, p. 114). That is, just because something occurs in the environment need not exclude it from playing a cognitive role. For what matters is not physical location but rather the contribution something makes to an agent's performance of a task. And where there

is parity of contribution, there should be parity of status (Wheeler 2010, p. 248).

Second, if PP is to apply, then objects in the environment and in-the-head processing should be understood in terms what is called their functional role. Functionalism can be defined as the claim that "what makes something a mental state of a particular type does not depend on its internal constitution, but rather on the way it functions, or the role it plays, in the system in which it is a part" (Levin 2008). Crucially, bodily details then only matter to the extent that they fulfill the requisite functional role. So, in the Tetris example, it is not important how the player holds the rotation device or moves their body when manipulating the device. What is important is rather that the device fulfills a role equivalent to in-the-head processing. Once this functional equivalence between outer and inner is attained, then the device can be understood as part of and so extending an agent's cognitive processing.

However, as Clark and Chalmers acknowledge (1998, p. 12), the Tetris example only applies to cognitive processes. No mention has been made so far of mental states. Clark and Chalmers remedy this via the following thought experiment.

Consider two people, Otto and Inga. Otto suffers from Alzheimer's disease and so has difficulty remembering things. In order to offset his poor memory, he always carries with him a notebook. Any time he learns something new, he writes it down in his notebook. Inga, on the other hand, does not have any such difficulty. Her memory functions normally.

Suppose then that Inga hears about an exhibition at the Museum of Modern Art (MoMA). She thinks for a moment about where MoMA is, recalls that it is on 53rd street, and then sets off to visit the museum. Suppose that Otto also hears about the same exhibition and he decides he wants to see it. However, rather than relying on his impaired biological memory, Otto instead employs his notebook. He looks in his notebook, retrieves the address, and then sets off to visit the museum.

According to Clark and Chalmers, both Inga and Otto have an unconscious belief about the location of MoMA. The only difference is that whereas Inga's belief is located inside her head, Otto's belief is partially located outside his head in his notebook. Nonetheless, this difference is not functionally relevant, insist Clark and Chalmers, since "the notebook plays for Otto the same role that memory plays for Inga. The information in the notebook functions just like the information constituting an ordinary [unconscious] belief; it just happens that this information lies beyond the skin" (ibid., p. 13).

In other words, Otto does with his notebook what Inga does with her biological memory. Indeed, Clark and Chalmers conclude that the moral of the Inga-Otto thought experiment is that, "when it comes to belief, there is nothing sacred about skull and skin. What makes some information count as a belief is the role it plays, and there is no reason why the relevant role could be played only from inside the body" (ibid., p. 14). So understood, Otto's mental state, that is, his unconscious belief about the location of MoMA, extends to include the contents of his notebook. Otto is thus an example of EM.

The Inga-Otto thought experiment has generated much debate within the literature on EM (see the introduction to Menary 2010a for an overview). Nonetheless, as with the Tetris example, PP plays a pivotal role in this thought experiment. For it is the alleged functional equivalence between, on the one hand, Otto's use of his notebook and, on the other, Inga's use of her biological memory, that ensures that Otto's mental state, e.g., his unconscious belief about the location of the museum, extends to include the contents of his notebook. Thus, if Clark and Chalmers are correct, then PP can be used to defend EM.

In what follows, the pivotal role PP plays within EM becomes more apparent when we consider what happens when PP is either minimized or removed altogether.

Second Wave Extended Mind

Second wave EM aims to minimize the role PP plays in making the case for EM. Understanding

what drives this desire to minimize PP will help clarify what is second wave EM.¹

Sutton (2010), for example, regards PP as problematic for two reasons. First, he asks us to consider the "individual differences in the amount and style of reliance on external resources [that] are often glaring in the ways people plan and engage in complex activities, such as writing an academic paper, shopping for a party, or chairing a department meeting. Do I memorize the train timetable in advance, or do I just turn up at the station and see?" (ibid., p. 199). This suggests, argues Sutton, that EM is more likely to be true of some people than others, since some people simply make more use of environmental objects or processes than others. But since PP only focuses on "generic features of cognitive states and processes" (ibid.) and so abstracts away from these concrete details, then it looks unable to account for these individual differences.

Second, PP "threatens to flatten out the important differences between cognitive artifacts" (ibid.). For if PP is correct, then the "particular nature of the external resources. . . does not really matter" (ibid.). Yet, according to Sutton, the differences between in-the-head processing and the roles played by bodily external objects may be crucially important. Indeed, these differences may help explain why some objects or artifacts and not others can transform the cognitive processing of agents. However, PP "fails directly to suggest study of idiosyncratic or peculiar features

¹ Section "Second Wave Extended Mind" of this chapter only focuses on Sutton's version of second wave. Another version of second wave not considered here is Menary's Cognitive Integration view (see Menary 2010a, b). This is the view that "internal and external vehicles are integrated into a whole" (Menary 2006, p. 329) and "it is bodily manipulation of the external vehicles themselves. . . where the cognitive work gets done" (Menary 2010b, p. 240). For Menary, cognitive processes are thus hybrid processes that constitutively involve the bodily manipulation of external vehicles. Cognition then is an ability (or abilities) of an agent to manipulate their immediate environment. In light of the discussion in this chapter (see section "Third Wave Extended Mind"), Menary's Cognitive Integration view would seem to be a Third Wave reading and so arguably incurs the problem facing other Third Wave readings, namely that it is not clear that it actually is a reading of EM.

of particular external symbol systems, or particular ways of interacting with them” (ibid., p. 200).

These concerns lead Sutton to argue for a complementarity view of EM. Sutton makes it clear that complementarity “subsumes and takes precedence over [PP]” (ibid., p. 206). Complementarity is the view that, “different components of the overall (enduring or temporary) system can play quite different roles and have different properties while coupling in collective and complementary contributions to flexible thinking and acting” (ibid., p. 194). This is understood to “permit and encourage quite different kinds of interaction and coupling and thus different kinds and degrees of extendedness” (ibid., p. 206). Thus, second wave EM can be defined as an attempt to make the argument for cognitive extension on the basis of complementarity and not parity considerations.

As an example of this, Sutton describes Tribble’s (2005) study of Shakespearean actors at the Globe Theatre. Such actors had to learn new lines in multiple plays in very short spaces of time, often without access to the plays themselves. This raises the following question: “How did the actors cope, and how did the companies rehearse and perform so many different plays under such pressures?” (Sutton 2010, p. 202).

Building on Tribble’s study, Sutton’s answer is that, “in the Globe physical architecture, artifacts, social structure, and the characteristics of the plays themselves combine to support the collective success of the company in performance” (ibid.). This is because, says Sutton, “the Globe’s artifacts worked to get actors to the right place at the right time for further environmental alterations (such as a particular line or event on stage)” (ibid., p. 203). That is, the Globe and its objects or artifacts were structured such that the actors simply had to remember to be at certain places at certain times, at which point lines could be quickly rehearsed and then subsequently performed on stage. Sutton claims that it was thus due to “[the actor’s] mastery of the cognitive resources of their highly structured dramatic environment” (ibid.) that they were able to memorize their lines. In which case, the physical architecture of the Globe can be understood as having complemented the actor’s internal cognitive

processing. Sutton claims that this is an example of Second Wave EM.

Note that on this second wave reading, the physical architecture of the Globe, contra PP, did not play a functionally equivalent role to any cognitive processes inside the actor’s heads. Indeed, given that this architecture is alleged to have transformed what the actors could do, in the sense that these actors could do things within that environment that they could not do outside that environment, then it follows that the architecture must have had properties distinct from in-the-head processing. Second wave thus seeks to minimize the role of PP and instead emphasize how the use of environmental objects or structures can be instances of transformative cognition.

However, as Ramsey notes, this change in emphasis renders second wave EM vulnerable to the following objection:

[w]hat [second wave] authors need, but do not really provide, is an argument for treating external structures as not only important for (and integrated with) cognitive systems during various cognitive tasks. . .but for also treating them as actually mental states. (Ramsey 2010)

This seems true of Sutton’s analysis of Tribble’s study. Recall the Hypothesis of Embedded Mind (HEMC). Sutton’s analysis looks closer to HEMC than EM. For the physical architecture of the Globe may simply have provided the needed prompt for the actor’s learning to take place. Nonetheless, the learning of the lines themselves could still be entirely dependent upon the actor’s internal resources. Importantly, this would be compatible with acknowledging the transformative role played by this architecture, namely, how outside that environment, the actors could not have learned their lines in the way that they did inside that environment. In short, while the physical architecture of the Globe may have scaffolded and in this sense complemented the actor’s internal cognitive processes, it does not follow that those internal processes were also extended to include that very architecture. Ramsey also raises this criticism of Sutton.

If this is correct, then it is not obvious that second wave actually is a reading of EM. Further support for this assessment comes from Sutton

himself, who claims that the advantage of second wave is primarily methodological. Second wave, insists Sutton, is “more an invitation to give detailed attention to these differences in specific contexts and case studies than a fixed new meta-physics of mind” (Sutton 2010, p. 206). Yet if second wave is only a methodological claim, that is, a claim about how and/or in what ways we should investigate cognition, then second wave is not a claim about cognitive extension, that is, it is not a claim about EM. In which case, by attempting to minimize the role of PP, it can be doubted that second wave actually is a reading of EM (Loughlin 2014).

Third Wave Extended Mind

Along with second wave, Sutton (2010) also describes a possible third wave reading of EM:

If there is to be a distinct third wave of [EM], it might be a deterritorialized cognitive science which deals with the propagation of deformed and reformatted representations, and which dissolves individuals into peculiar loci of coordination and coalescence among multiple structured media. . . [T] his third wave would analyze these [inner and outer] boundaries as hard won and fragile developmental and cultural achievements, always open to renegotiation. (2010, p. 213)

Kirchhoff (2012, pp. 291-293) picks out three key themes from the above quote from Sutton.

First, Kirchhoff understands the phrase “deterritorialized cognitive science” to mean a cognitive science whereby the boundaries between what is internal and what is external to an agent are always porous or open-ended. Second, “deformed and deformatted representations” refer to how enculturation, that is, the process whereby human agents become immersed within a sea of cultural norms and values, can transform the human brain, which points towards the inherent plasticity of the brain’s representational capacities. Third, “dissolves individuals into peculiar loci of coordination and coalescence among multiple structured media” suggests that cognition should no longer be understood to be organism centered but rather as something highly distributed, capable of being brought into existence as

and when softly assembled “loci of coordination” are actualized.

These three themes, if accepted, indicate how a third wave reading removes any lingering commitment to PP. For if enculturation points towards the inherent plasticity of the brain, and cognition is no longer understood to be organism centered, then the role that objects or artifacts play in an agent’s performance of a task cannot be understood in terms of their equivalence to in-the-head processing. Indeed, if agents themselves are highly distributed, softly assembled loci of coordination, then the very idea that we need to look inside the head to determine what is part of the mind is a nonstarter.

However, this removal of PP raises a key issue for a third wave reading. For what happens when you decentralize cognition in this particular fashion? Kirchhoff and Kiverstein (2018) offer a possible answer to this question.

According to Kirchhoff and Kiverstein, a third wave reading begins by rejecting any notion that the properties of what is bodily internal to the agent and/or what is bodily external to the agent are fixed and/or static. Instead, “through ongoing participation in culturally organized activities with other people” (ibid., p17), agents are transformed such that what is internal to the agent is reformed and reformatted “through a network of practices in which the individual participates” (ibid., p17). Cultural practices then are not simply background conditions in the formation of an agent’s various cognitive processes. Rather, cognitive processes are themselves constituted diachronically, for they are “dynamic and temporal trajector[ies] of activity” (ibid., p21) always forged within wider practices.

This then impacts on the agents that embody those activities. Gone is the idea of lone individuals recruiting objects or artifacts in their environments in order to complete certain tasks (think of Otto and his notebook). Instead, agents are now widely constituted “bio-cultural system[s]” (ibid., p20), realized as much by the practices in which they are enculturated as by anything happening inside their heads.

In order to illustrate this, consider the following example (which is not taken from Kirchhoff

and Kiverstein). Suppose you sit down at a desk with a blank sheet of paper in front of you. You have decided to write a letter to a close friend. However, you have no clear idea about what you want to say or how you want to say it. You begin, “Hi Catherine.” You write a few words but you cross them out. You then write a few more, which you subsequently keep. In this hesitant back-and-forth between writing and editing, what you want to say slowly starts to emerge from what you write. This is how the letter is written.

Following the sort of third wave reading of EM just described, when composing the letter in this manner, your cognitive processing is decentralized, in the sense that you only loosely coordinate what is happening, hence why what you want to say can slowly emerge from what you write. But if so, then your processing cannot be sourced to any one moment. Instead, your cognitive processing is a dynamical process, that is, one that unfolds and develops over time. Moreover, this dynamical process is only possible because of your enculturation within a wider practice, namely the practice of using pen and paper to compose letters to friends. Indeed, it is your very enculturation within this practice that makes you a cognitive agent and so makes what you are now doing a cognitive activity.

Recall then the doubts previously raised as to whether or not second wave was an example of EM. There it was claimed that second wave might be better understood as a version of HEMC (see section “[Second Wave Extended Mind](#)”). The same worry, however, does not apply to third wave. For if wider cultural practices can play constitutive roles in the formation of agents and their cognitive activities, then third wave cannot be read as a version of HEMC. Environments, according to third wave, do much more than simply embed minds.

However, another issue presents itself. Following a third wave reading, you are not a lone individual recruiting objects or artifacts in your environment in order to complete certain tasks. You are instead realized by the practices in which you are enculturated. But if so, then it no longer makes sense to think of “you” as some bounded entity. You are instead, to borrow Sutton’s words,

a “loci of coordination,” softly assembled and distributed across multiple media. And what applies to you must also apply to your mind. Yet if your mind can no longer be understood as a bounded entity, then what exactly extends? Indeed, if agents and their minds are highly distributed and decentralized, as some proponents of third wave contend, then all talk of extension begins to look otiose. It is thus not clear that third wave actually is a reading of EM.²

How then should third wave be read? One option is to read third wave as an enactivist proposal.

Enactivists prioritize the role of action, and so enactivism can be understood to be a branch of action research. Most enactivists accept that mind and experience are essentially dynamical processes realized as and when agents interact with and/or have interacted with their environments. However, there is little agreement among enactivists as to how this proposal should be developed. Some root it in the autopoietic nature of autonomous systems and their sense-making activities (Thompson 2007). Others focus instead on the role of what are called “sensorimotor contingences” enacted during perceptual experience (O’Regan and Noë 2001; Noë 2004; Loughlin 2018b, 2019). Still others examine social and linguistic practices and how they can scaffold distinctive forms of human thought (Hutto and Myin 2013, 2017). Given that third wave views the mind in terms of dynamically unfolding activities, then it is plausible to frame such a view as akin to one or perhaps a number of these competing enactivist proposals.³

²Note that this criticism of third wave does not consider many of the details of Kirchhoff and Kiverstein’s defense of Third Wave Extended Mind. For example, they appeal to predictive processing models of the mind and the role such modeling can play when considering whether or not the boundaries of the mind extend. However, determining whether or not these details can in fact resolve the criticism raised here is beyond the scope of the present chapter.

³Someone who pursues this line is Gallagher (2017). Indeed, Gallagher proposes to bring EM and enactivist views into alignment via a third wave reading of EM. Gallagher also shows the interesting overlap between EM and the work of various American Pragmatists. However, following the discussion in this chapter (see section “[Third](#)

An objection to this, however, may be that most enactivists view mind and experience as first and foremost organism centered, although not of course as organism bound. Yet this looks in opposition to third wave's insistence that cognition is not organism centered (Ryan and Schiavio 2019). If this objection is correct, then it may not be clear how third wave should be read, neither as version of EM nor as a version of enactivism.

Another option then is to frame third wave EM in terms of Glaveanu's (2018) notion of the possible. This could be an instance of using the notion of the possible in philosophy. If so, then minds could be understood to be, in Glaveanu's words, "creative actions...[that] open up, exploit and expand the possible for both self and others" (ibid., p. 12). Minds thus neither extend to include objects in the environment nor are enacted via engagement with those objects. Rather, by being enculturated within wider practices, minds are those horizons and potentialities created by those very practices. Recall the previous letter example. It is only by being enculturated within a practice of writing letters that what you think, feel, desire, etc. can emerge out of and so be softly assembled by your act of composition. However, if framed in these terms, then third wave EM is indeed radically distinct from both EM and enactivism.

Summary

Extended Mind (EM) is usually understood to be a claim about cognitive extension, that is, it is usually understood to be the claim that the boundaries of the mind can occasionally extend to include objects in the environment. The central theme of this chapter has been that understanding EM in the above fashion helps zero in on how this claim should be defended.

For example, Clark and Chalmers' Parity Principle (PP) can be viewed as playing a pivotal role

in defending EM. For as both second wave and third wave readings reveal, once PP is minimized, as is the case with second wave, or removed altogether, as is the case with third wave, then it is no longer clear that we are still talking about EM. Hence, if EM is understood to be a claim about cognitive extension, then PP should be regarded as key to defending that claim.

Definition

Ray Bradbury's 1953 *Fahrenheit 451*, with the complacency of its television-anesthetized society being guarded by book-burning "firemen," is an exploration of the possible that, despite the passage of decades, still delights, terrifies, and enlightens just as much as it did generations ago, for the human mind of today – or tomorrow – holds much the same peril and the same promise it always has. This cultural touchstone simply cannot – and of course *should* not – be ignored. The modern world, after all, still is witness to ever-accelerating technological advances that can make life easier and faster, debates so polarized and exhausting that both distributors and

consumers of entertainment recoil warily from the wrath of pressure groups and even the mere struggle of argument, and the mass exploitation of myriad diversions that can lure so much more enticingly than the duties of intellectual and moral responsibility. Yet Bradbury's masterful *Fahrenheit 451* will continue to warn discerning readers of the lurking possibility of the easy slide toward inhumanity, the decline of thought, and censorship even as it celebrates the possibilities of the human – and humane – mind.

Introduction

Ray Bradbury's 1953 *Fahrenheit 451*, with the complacency of its television-anesthetized society being guarded by book-burning "firemen," is an exploration of the possible that, despite the passage of decades, still delights, terrifies, and enlightens just as much as it did generations ago. Why? Because even as technologies come and go, politics move pendulum-like with changing social mores, and global power structures shift like the breakup of Pangea, truly there is no new thing under the sun, and the human mind of today – or tomorrow – holds much the same peril and the same promise it always has. The disturbing possibilities highlighted by *Fahrenheit 451* thus make it a book that readers cannot help reading, pundits cannot help pointing to, critics cannot help analyzing, and teachers cannot help assigning. For good reason, this cultural

touchstone simply cannot – and of course *should* not – be ignored.

Kingsley Amis famously termed *Fahrenheit 451* “a fast and scaring narrative” (94). At about only 50,000 words, the slim little novel is swift partially due to a style that sometimes “hustle[s] the reader through with either crisp brevity or irresistible monosyllables” (McGiverson, 2013a, 12) and at other times uses rollicking long sentences with gusto. The speed also stems from structural choices – the lack of conventional chapters, for example, and the construction of “easily digestible scenes...leading easily from one to another” – resulting in “something of a narrative slippery slope effect” (McGiverson, 2013a, 4). Such swiftness accentuates the “scaring” nature of the plot, and yet the truly terrifying aspect is how plausible almost everything in the book is, how very possible.

Technology As Possibility

The portrayal of technology in the novel is interesting to investigate through the lens of the possible. Although Bradbury, in the words of Marvin E. Mengeling, “is no reactionary, antimachine ‘nut’” (98), neither does his fiction usually display or explore technology with much rigor. Indeed, amid the modern world of the near future, the “trappings” of fairy tale, such as the “crystalline description[s]” (115) that Eric S. Rabkin notes in *The Martian Chronicles*, occur in *Fahrenheit 451* as well, as does noticeable imagery involving other traditionally ancient fairy-tale materials. Crystal itself, for example, can be seen in the construction of pill bottles (Bradbury 43), television screens (Bradbury 76, 122), and homemade radio apparatus (Bradbury 118), along with a metaphorical chandelier (Bradbury 121) and a simile for the face of Clarisse, the teenaged next-door neighbor who so inspires unknowingly disaffected fireman Guy Montag (Bradbury 37). The ominous firehouse, “full of glitter and shine and silence,” is described as a place “of brass colors, the colors of coins, gold and silver” (Bradbury 62). The nozzle of Montag’s kerosene-spewing fire hose depicted on the very

first page of the novel is brass (Bradbury 33), as are the firehouse pole (Bradbury 54, 55, 65, 133, 137), the firetruck’s kerosene tank and its identifying numbers as well (Bradbury 137, 138), the pipe of the avuncular yet sinister Fire Captain Beatty (Bradbury 83), and the slot to the handy household incinerator in Montag’s home (Bradbury 129). Fairy-tale silver – though the color rather than the metal itself – gleams not only in the reflection in Montag’s brooding moonlit eyes (Bradbury 47), but also as a replacement for the more modern steel or chrome surely being seen in Montag’s apparently regulation-issue igniter disc (Bradbury 43), the robotic toaster of in his kitchen (Bradbury 48), firemen’s hatchets (Bradbury 66), the firetruck rail (Bradbury 137), and the procaine needle of the Mechanical Hound that hunts down any dissidents (Bradbury 55). These materials are the stuff of fairy tales – seen in glass coffins, brass armor, silver swords, and the like – but they also are old-fashioned, and they do not cause readers estrangement as the use of truly novel and futuristic materials might. Instead, such familiar, even anachronistic descriptions in the book’s science-fictional setting help ease readers into the plot, which in many ways already is so frighteningly possible.

When Bradbury does showcase technology in this science fiction novel of a near-future United States, he uses no gleaming rocketships for flying to porcelain Martian chess-men cities, no time machines, or no footpaths of antigravity metal for hunting tyrannosaurs. His technological markers of a future imagined from 1953 often stay much closer to home, such that the reality of the possible has caught up with them fairly quickly. The tiny “Seashell Radios” tamped into people’s ears to drown out the world with music or with game shows that fill audiences “so damned full of ‘facts’ they feel stuffed, but absolutely ‘brilliant’ with information” (Bradbury 90), for example, are the wireless earbuds of today. The full-wall television screens that cost a third of the yearly salary of a fireman such as Montag (Bradbury 50) – and which often cover three or even four walls of a rectilinear living room, so totalizing that any program “rushes you on so quickly to its own conclusions your mind hasn’t

time to protest, “What nonsense!” (Bradbury 112) – are only a notch or two up from either our current big-screen versions or the more expensive home theater systems, and almost all adult and even adolescent Americans now carry a device that, among other uses, will function as the once-miraculously miniaturized “portable viewer” (Bradbury 173) or the “television screen the size of a postal card” (Bradbury 158) used by those dogged few characters in the novel who are not addicts to complete television immersion. The stomach-pumping made necessary in the novel by the fast-paced society’s all-too-common overdoses is, as the uninterested technician explains, an “ancient” process (Bradbury 45), but it utilizes, essentially, an endoscopic camera and helmet-mounted virtual reality display (Bradbury 44) that are only fractionally more advanced than similar equipment of today. Even Bradbury’s imagining of “robot tellers” (120) dispensing money at the all-night banks of this restless future society predates the now-commonplace automated teller machine by only a decade or two, and while the fingerprint reader in “the glove hole of [the] front door” (Bradbury 40) is not yet common in the real world, the novel’s automated door announcer (Bradbury 82, 97, 100) actually is not as sophisticated as the front door video security apparatus of many modern-day homes. Thus, although Bradbury has extrapolated technical advances into a suitably science-fictional future, he generally has not made them *too* advanced.

Occasionally, though, the book does toss out certain flashier pieces of technology. Perhaps the most tangential is the kitchen toaster incorporating “a spidery metal hand” that automatically butters and then serves the toast (Bradbury 48). Another, a similar minor throwaway item, but one a bit more central to the plot, is the extra “converter attachment” that – for an extra charge, naturally – helps personalize the ubiquitous wall-sized television screens by making an announcer say the viewer’s name as its “special spot-wavex-scamblers also cause[s] the televised image, in the area immediately about his lips, to mouth the vowels and consonants beautifully” (Bradbury 93). Another technological achievement integral to Bradbury’s themes is the jet car, which thrill-seekers might

“race on the edge of town at midnight and the police don’t care as long as they’re insured” (Bradbury 50). A similarly science-fictional machine of transportation, less “sexy” than a jet car and yet probably more difficult to engineer, is the “vacuum-underground” (Bradbury 106), or “air-propelled train” of the subway (Bradbury 34). The public might have “motorcycle helicopters” (Bradbury 91), while even more ambitiously designed police vehicles turn from cars to helicopters and back to cars again as needed (Bradbury 150–151). Some of this, obviously, is pure whizz-bang fluff. In addition, although American jet bombers have passed overhead ominously in the night a number of times during the novel, as common to its characters as swept-wing B-47s flying in and out of Strategic Air Command bases might have been to the book’s original Cold War readers, there also is a single reference to the cryptic “enemy disks” (Bradbury 120), and when war finally comes, the enemy’s nuclear bombs fall from hypersonic jets flying 5000 miles per hour (Bradbury 183), a figure that seems chosen both as an echo of the big round numbers of fairy tale and also as a futuristic tenfold increase over then-current speeds. Such pieces of technology, each of which, except for the jet car, is mentioned literally only once or twice in the novel, help engender a science-fictional sense of delight without casting the reader into a future seeming too strange or beyond the possible.

Even the ghastly Mechanical Hound, which appears several times in *Fahrenheit 451* and which, even more than the book’s ubiquitous immersive televisions, may be its most memorable technological artifact, is presented with this dual perspective. On the one hand, almost nothing else could be as friendly and reassuring as the resident dog of an old-fashioned firehouse. And even though this roboticized simulacrum sometimes is discussed “in terms of modern materials, like steel and nylon and rubber” (McGivern, 2013a, 12), it also reflects the fairytale materials of “ruby glass” and brass and copper (Bradbury 54), and at the same time that it emits a modern “electrical sizzle,” it also gives off a quaintly old-fashioned “scraping of metal, a turning of cogs that [seem] rusty and ancient with suspicion”

(Bradbury 55). On the other hand, the Hound truly is the height of robotic science. With its snout sensors that can sniff out the “chemical balances and percentages” of a particular human body, the Hound “targets itself, homes itself, and cuts off” (Bradbury 56)... the shutdown occurring only after it has “inject[ed] massive jolts of morphine or procaine” (Bradbury 55) into the bibliophile who had escaped the police or the firemen. The Mechanical Hound is science-fictional whizz-bangery of the most horrifying sort, and yet even now, the possible has almost caught up with Bradbury’s fiction, with legged robots being researched for military applications (DARPA), as is the next step of developing autonomous vehicles and weapons controlled by their own artificial intelligence (Lockheed Martin).

Social Decline As Possibility: Causes

The truly terrifying aspect of *Fahrenheit 451*, of course, is not that its imagined technology will become possible – aside from the fact that much of it has, after all – but that the attitudes of its society will grow widespread in the real world as well. It can be very easy to blame technological advances, particularly the television in its ever-larger incarnations, for turning a past of curiosity and freedom of thought into a future of willful ignorance and repression. Robert Reilly, for example, terms the novel “a frightening picture of how the products of science can destroy persons and human values” (67). Such blame is slightly misplaced, though. After all, does technology itself actually decide what and how people will think? No – technology may help open or close certain possibilities, but it itself does not do the thinking or make the decisions in our personal, political, and moral lives. Captain Beatty, in a memorable discussion at Montag’s sickbed after the target of their most recent raid has burned herself to death before them rather than abandon her collection of forbidden books and magazines, explains that for helping create a society that has replaced thought with complacency, “[t]echnology, mass exploitation, and minority pressure carried the trick, thank God” (Bradbury 87). Any discussion of the true

warning of *Fahrenheit 451* should examine these threats with care.

Technology

The technological acceleration of the modern era helped lead, Beatty tells Montag, to what with wonderfully bland irony he terms their “happy world as it stands now” (Bradbury 91), a world of compulsive pleasure-seeking... and yet also endemic suicide, violence in the streets, and the unacknowledged threat of yet another nuclear war. Contrasting the “slow motion” of the “Nineteenth-century man with his horses, dogs, carts” with their own faster-paced world in which all “unnecessary, time-wasting thought” has been cast off (Bradbury 85), the suave Fire Captain asserts aphoristically that “The zipper displaces the button and a man lacks just that much time to think while dressing at dawn, a philosophical hour, and thus a melancholy hour” (Bradbury 85). This sounds very persuasive, and the world of jet cars, flying motorcycles, and traffic blasting “a hundred miles an hour” not just through the countryside but even “across town” (Bradbury 76) initially seems to show technology run amok.

Yet Faber, the former English professor who ultimately mentors Montag in the fireman’s quest to understand what it means to be truly human, shows that Beatty’s evaluation is not quite correct. Regarding the ubiquitously yammering televisions, for example, although Faber admits that even he “ha[s] never been able to argue with a one-hundred-piece symphony orchestra, full color, [and] three dimensions” of a multiwall television room (Bradbury 112), still he owns a tiny television he can “blot out with the palm of [his] hand” (Bradbury 158). The book-memorizing intellectuals Montag meets after his escape from the city are similar, keeping a small “portable battery TV set” (Bradbury 173). Crucially, when Montag first tells Faber, “We have everything we need to be happy, but we aren’t happy,” the disenchanted fireman naturally supposes that “books might help” (Bradbury 110), but the professor corrects him: “The same things *could* be in the ‘parlor families’ today. The same infinite detail

and awareness could be projected through the radios and televisions, but are not” (Bradbury 110–111). The issue, then, is not a matter of technology itself but one of humane or inhumane use.

Really, almost none of the gadgets of *Fahrenheit 451* is innately harmful, and they all could be put to humane uses as readily as they are to inhumane ones. As Faber implies, the “infinite detail and awareness” inherent in modern electronic mass communication could be used for education rather than as intellectual anesthetic: in investigative journalism, in documentaries on topics from art to history to nature, and in educational children’s programming. In terms of the so-called education of public school, Clarisse describes “[a]n hour of TV class” and “four more hours of film teacher,” but although in the novel “they just run the answers at you, bing, bing, bing” (Bradbury 59), it does not have to be this way. College courses today, after all, occasionally use similar technology for delivery through videoconferencing or even with the less advanced option of noninteractive-recorded lectures, and presumably these are attempts to foster true learning rather than simply ensuring that students “never ask questions” (Bradbury 59); in the words of Faber, this higher goal *could* be pursued in the novel but is not. In fact, even the novel’s most insidious pieces of technology have these dual potentials. The Mechanical Hound could have been programmed for search and rescue operations instead of State-sanctioned murder, for example, and nuclear fission could have been used in power plants to generate electricity rather than in bombs designed to destroy cities or, at worst, in weapons reserved for deterrence rather than being the first choice for a nation that has “started and won two atomic wars since 1960” (Bradbury 101). The possibilities lead both ways.

Minority Pressure

If technology is more an enabler rather than an actual cause of the decline of thought in *Fahrenheit 451*, Captain Beatty’s discussion of “minority pressure” as a cause – the term *minority* indicating any type of group rather than only racial or ethnic

ones – is more convincing, and rightly so. Whereas Bradbury in stories of just a few years prior to *Fahrenheit 451* depicted censorship as being motivated by “the rather . . . juvenile bogeyman” (McGiverson, 2017, 55) of a government that for some reason wants to ban fantasy literature, Christmas, and Halloween, here he has moved beyond what a government may force upon the populace to the pressures of the market and to public taste or lack thereof. As Beatty explains, “The bigger your market, Montag, the less you handle controversy, remember that! All the minor minor minorities with their navels to be kept clean. Authors, full of evil thoughts, lock up your typewriters. They *did*. Magazines became a nice blend of vanilla tapioca. Books . . . were dishwater. No *wonder* books stopped selling. . .” (Bradbury 87).

The occasional narrowing of discourse due to a shying away from controversy or the reactions, real or imagined, of readers or audiences can be seen in our own world, of course. On the one hand, for example, it is difficult to argue against replacing old titles like *mailman* and *policeman* with *mail carrier* and *police officer*, since these professions indeed are no longer male-only. On the other hand, political correctness sometimes is stretched so far that even a mere differing opinion is labeled indignantly as hate or as the increasingly popular [*insert category here*]-shaming. In these latter instances, when writers or publishers in trying to avoid backlash simply refuse to present certain topics or opinions, “the damage of minority pressure is caused primarily by intolerant pressure groups and secondarily by the controllers of communication who follow their wishes,” with audiences and readers often being “unaware that pressure groups influence what they watch, hear, and read” (McGiverson, 1996, 249). When discourse of a potential controversy is not even presented due to fear of reaction from proponents of whichever side of an argument it may be, members of a society have little motivation to explore further.

Mass Exploitation

Mass exploitation, however, is a far different matter, for the masses cannot be exploited except with

some degree of willingness. It is one thing not to know, after all, but it is quite another to *choose*. “Serenity, Montag,” croons Beatty. “Peace, Montag. Take your fight outside. Better yet, into the incinerator” (Bradbury 89). Yet although avoiding the discomfort of contentious debate about politics, foreign policy, social issues, and the like may be the public’s occasional response to argumentative or offended pressure groups, the threat to thought is not just the public’s flight from intellectual challenge but its actual *chasing after* mind-numbing entertainment of perhaps less than zero worth – less than zero in that the surfeit of easy gratification makes the mind ever less accustomed to anything but the quickest and simplest of pleasures. In his pep talk trying to reinspire Montag to the life of burning, Beatty rhetorically asks “[w]hat. . . people want in this country, above all,” and then provides an answer as grim and dehumanizing as it is manically pleading: “People want to be happy, isn’t that right? Haven’t you heard it all your life? I want to be happy, people say. Well, aren’t they? Don’t we keep them moving, don’t we give them fun? That’s all we live for, isn’t it? For pleasure, for titillation? And you must admit our culture provides plenty of these” (Bradbury 89). Titillation and pleasure, of course, are the *only* things this culture provides, for back when the public still had a choice, they were the only things people ended up buying.

According to Beatty, the “publishers, exploiters, broadcasters” of the pre-censorship days “pump[ed]” the “centrifuge” of mass communication, narrowing down the content of their wares further, ever further, until nothing of consequence was left: “Digests-digests, digests-digests-digests. Politics? One column, two sentences, a headline! Then, in mid-air, all vanishes!” (Bradbury 85). Yet this narrowing is not something forced upon a public hungry for information and intellectual challenge; the public itself must *desire* its television walls to show “pretty colors running up and down. . . like blood or sherry or sauterne” (Bradbury 86) rather than, say, Edward R. Murrow. As Beatty points out even when ostensibly discussing the effects of pressure groups, the contents of printed and electronic

media are greatly dependent upon “the market” (Bradbury 87), in which readers and viewers choose what to engage, whether challenging and uplifting or mind-atrophying, by voting with their dollars. By the time of the novel, readers have chosen only “comics, the good old confessions, . . . trade journals,” and “the three-dimensional sex magazines, of course” (Bradbury 87), along with television that brings only soap operas so cheap and slipshod that “*nothing’s* connected up” (Bradbury 75), surreal visual flights of almost psychedelic fancy, cartoon characters dismembering each other “to the accompaniment of immense incoming tides of laughter,” and jet car demolition derbies where wildly thrown bodies delight the audience at home (Bradbury 122).

Thus, although the American government in *Fahrenheit 451* has turned to censorship to hold off “the small tide of those who want to make everyone unhappy with conflicting theory and thought” (Bradbury 91), Beatty’s discussion of minority pressure and, more important, mass exploitation shows that the original impetus “didn’t come from the Government down. There was no dictum, no declaration, no censorship to start with, no!” (Bradbury 87). Lest readers imagine that the slippery Beatty is not to be trusted here, later in the plot Bradbury has Professor Faber confirm the judgment. Although Faber “saw the way things were going, a long time back,” he “did not speak up and out” (Bradbury 110). “How like a beautiful statue of ice it was, melting in the sun,” laments Faber of a culture that once valued thought and curiosity, with “the newspapers dying like huge moths. No one *wanted* them back. No one missed them” (Bradbury 117). Indeed, “[t]he public stopped reading of its own accord,” according to Faber, and now the book-burning firemen are “hardly necessary to keep things in line” (Bradbury 115).

When “[s]o few want to be rebels anymore” (Bradbury 115), and “the public, knowing what it want[s], spinning happily” (Bradbury 87), simply wallows in mindless television and drugs and “more of everything to do with automatic reflex” (Bradbury 91) rather than actually examining itself and the world around it, American society

has no hope of being saved from within. Only nuclear war, the rather smaller and not completely world-annihilating kind that was becoming less and less possible to imagine even as *Fahrenheit 451* was being written, can free people from the hedonistic trap they have created for themselves. Initially, as war looms, Faber is doubtful that the covert groups of dissident book-memorizers will accomplish anything useful in the postwar world: “What? Men quoting Milton? Saying, I remember Sophocles?” (Bradbury 116). On the literal eve of the enemy attack, however, with Montag exposed as a bibliophile criminal, and on the run after having escaped by killing Beatty, the once-tired Faber is “alive for the first time in years” (Bradbury 157). Readers may have doubts about whether Montag and the wandering group of book-memorizing former professors who take in the fugitive truly would be able to rebuild a better world from the postnuclear ashes, but Bradbury’s conclusion, with its Biblical references of “[a] time to break down, and a time to guild up” and the “*tree of life*” whose “*leaves . . . [are] for the healing of the nations*” (Bradbury 190), shows that this hope is what he intends. With the histories, literatures, and philosophies of the past remembered once more, Montag’s group hopes to break the self-destructive cycle of the phoenix, for unlike that mythical bird, humanity can “know all the damn silly things we’ve done for a thousand years” and thus perhaps can learn to “stop making the goddamned funeral pyres and jumping in the middle of them” (Bradbury 189).

Summary: The Possibilities Now

How possible is the nightmare world of *Fahrenheit 451* now, really? On the one hand, it seems extraordinarily unlikely that full-fledged censorship of the Nazi-esque book-burning variety would be instituted in the United States, or even that the Great Firewall of China would be replicated here to rein in our wildly freewheeling Internet. Although our technological advances have mostly caught up with those of Bradbury’s warning tale that from the perspective of 1953

“look[ed] only a century or less into the future” (McGivern, 2013b, 73), after more than 75 years we still have not descended into the disconnected inhumanity portrayed in the novel. Perhaps some of this is due to the widely read *Fahrenheit 451* itself. Although other classic dystopias such as George Orwell’s *1984* (1949) and Aldous Huxley’s *Brave New World* (1932) cannot help but remain entertaining and enlightening, it has always been *Fahrenheit 451*, whose plot is grounded not in ruthlessly repressive dictatorship or in a far future seeming-paradise maintained by the dehumanizing caste structure of merciless genetic programming but in the familiar realities of American society, that warns of perils still so very possible.

The modern world, after all, still is witness to ever-accelerating technological advances that can make life easier and faster, to debates so polarized and exhausting that both distributors and consumers of entertainment recoil warily from the wrath of pressure groups and even the mere struggle of argument, and to the mass exploitation of myriad diversions that can lure so much more enticingly than the duties of intellectual and moral responsibility. And whether tomorrow’s political factions are the Republicans and the Democrats or the Ins and the Outs, and whether computers of the future are worn on the wrist or woven from nanofibers along our own nervous systems, Ray Bradbury’s masterful *Fahrenheit 451* will continue to warn discerning readers of the lurking possibility of the easy slide toward inhumanity, the decline of thought, and censorship even as it celebrates the possibilities of the human – and humane – mind.

Abstract

Feminism is a very transforming unarmed revolution of the twentieth century, still facing new and complex challenges in the twenty-first century (Chesler and Hughes 2004; Coronado 2017; Fernández 2018). It encompasses women’s struggles – half of the population of the planet – against the historical violence and oppression exerted by patriarchal dominant structures in different geographical contexts and aspects of

the existence: family, work, political, economic, academic, urban, rural, among others. Feminism strives for making visible and valuing the roles that diverse women play in society, promoting the recognition of their human rights and proposing other ways of thinking, inhabiting, and acting in the world. It has brought key concepts and methodologies to light, transforming different fields of knowledge in social sciences, politics, economics, and health research, among others, with important contributions to the development of public policies.

However, feminism achievements are far from being attained, especially by poor and racialized women from the Global South. The *South* understood here not as a geographical concept – even though the great majority of impoverished populations live in countries of the Southern hemisphere – “but as a metaphor of the human suffering caused by capitalism and colonialism at the global level, as well as the resistance to overcome or minimize such suffering” (Santos 2012:43). Thus, feminisms from the South emerge in plural from different anti-colonial and anti-racist movements, in which exploited and racialized women struggle for just and equitable societies. In this chapter, we want to call the attention on how Latin American women from Indigenous, Afro-descendant, and Peasant Mestizo origin are creating other possible ways of relating in society and with nature by: (1) debriefing the sequels of colonialism and racism in their personal, community, and societal lives; (2) bravely facing current predatory approaches to nature from hegemonic extractives economies, which are destroying community territories and displacing their inhabitants from the access to water and land; and (3) actively questioning and transforming patriarchal traditions at the interior of their own families and communities.

Feminism – Facing Centuries of Exclusion: A Brief Overview

Time has come to stop the severe laws of men preventing women from studying science and other disciplines. (Christine de Pisan in 1405, cited by Pérez Sedeño 2000: 1)¹

If women' voices had been taken into account, the world today would be wiser. We would have learned from the wisdom of the nine million women burned by the Inquisition, who were so knowledgeable that were condemned as witches. (Nuria Varela 2005: 173)²

Feminism is not, as popularly believed, a social movement against men but against *patriarchy*, the political, economic, religious, and social organization based on the idea of authority and leadership of men over women, husband over wife, father over mother and children, and the line of parental descent over the maternal one. Patriarchy emerged as a historic seizure of power by men, who appropriated the sexuality and reproduction of women and their offspring, while creating a symbolic order through myths and religion that naturalized and perpetuated *androcentrism*, the masculine point of view, as the measure of all things, while the feminine – and the woman – was undervalued (Bachofen 1998; Beauvoir 1998; Castells 1998; Varela 2005).

The European and Anglo-Saxon nations – which erected themselves as superior to other peoples and cultures from America, Africa, and Asia since the sixteenth century – came themselves from ancient androcentric traditions that considered women as inferior. Women were persecuted during the Inquisition, an authoritarian regime supported by the Catholic Church but also by the Protestants in Europe and abroad. Nonetheless, Bacon, “the father of modern science,” considered Nature to be the bride, the one who needs to be dominated, shaped, and subdued by the mind of the scientist, characterized by his virility and masculinity, different from the female creature, portrayed as “passive, weak, expectant” (Keller 1991).

The Enlightenment was no more generous: the precursors of universal freedom and equality, promoted during the French Revolution, excluded women from the newly acquired political rights and ordered the dissolution of women's clubs where they were discussing their rights to education, work, and voting, and against the abuses within marriage. In 1793, Olympe de Gouges, who had published 2 years before the “Declaration of the Rights of Women and the Citizen,” was guillotined (Varela 2005). Both in Europe and in its colonies, women's access to academic institutions was not allowed until the end of the nineteenth century and in some countries until the middle of the twentieth century; the same for the right to vote, to freely choose a partner or get divorced, and publicly lead business and government instances (Arnot 1995; Harding 1996, 2000).

The expansion of capitalism and industrialization during the nineteenth and twentieth century demanded a greater workforce that was supplied by women. However, their participation in the labor market was not reflected in women's attainment of (1) *civilian rights* such as freedom of the person, expression, thought, and belief; the right to property and to enter into valid contracts; (2) *political rights* to participate in the exercise of power through political representatives or as voters; and (3) *social rights* to a minimum of welfare, fair salaries, and economic security, among others (Arnot 1995; Estevez 2018). Of course, these rights were (and still are) almost impossible to achieve for enslaved, exploited, or impoverished women.

As incredible as it may seem, it is up to the final decades of the twentieth century that women's movements began to see the suppression of many forms of exclusion from political, educational, and scientific institutions. Women were gradually entering into predominantly masculine fields of action and knowledge such as mathematics, engineering, or biomedical sciences. Still, their equal participation in politics, academics, or leading organizations is limited (ONU 2018). The matter is not only numerical: the referential framework of knowledge, action, and power remains androcentric, racist, and sexist (Hill

² Our translation to English from Spanish.

Collins 2012). However, as Harding (1996) pointed out, women feminist academics have been the ones noticing the androcentric biases in the scientific work, both in the definition of scientific problems as well as in research concepts, theories, methods, and interpretations.

Diverse Feminisms: Common and Different Struggles

To better understand feminisms from the South, it is precise to acknowledge that the feminist movement is not a monolithic program. It has contributed to enhancing the conception and implementation of women's human rights but from different historical moments and approaches. For example, the *liberal feminism* emerged in Western society from women's struggle for equal rights in all social, economic, and institutional spheres, from the suppression of labor discrimination to their increasing participation in public life. To them we acknowledge the recognition of sexual and reproductive rights, the creation of special provisions for the care of young children, as well as the facilitation of women's access to educational institutions and academia (Castells 1998; Varela 2005). However, from *feminism of the difference or radical feminism*, some scholars argued that women's greater inclusion in fields of male domination was not confronting and transforming the patriarchal society. This discussion deeply re-signified the notion of *gender* as a cultural construction, non-biological, further challenging the historical determinism that reduced women's role to the "feminine" domestic, male satisfaction, and reproductive sphere. It also unveiled the poverty and discrimination of women from diverse ethnic, racial, linguistic, and sexual groups, and their struggles to get them visible within society (Hooks 1984; Arnot 1995; Lamas 1996; Estevez 2018).

Questioning the patriarchal imperative has also inspired men's movements towards transforming the authoritarian and pathological views of a masculinity that has inhibited their expression of affection and feelings, as well as the possibility

of exercising non-oppressive power. Feminism, by questioning the biological determinism, has also contributed to rethink the notion of "masculinity" and the emergence of "**new masculinities**" against the oppressive relationship over women imposed on men by patriarchy (Hooks 2004; García 2015). There is a growing number of men working on deconstructing the historical role assigned to them based on a dominant and authoritarian position that has had a negative effect on their affective life and work relationships. This has propelled changes on social life and policies so men could also share domestic and care responsibilities; develop collaborative (non-competitive) relationships in different spaces of the existence, including the academic work; solve conflicts without violence; and join feminist, ecological, and ethnic efforts towards respect for nature and their human rights (Geldres et al. 2013).

Feminism has also contributed to put forward conceptual tools towards the recognition of the human rights of other gender identities in the public sphere, such as the LGBTQ+ communities, stigmatized for not being part of the binary division of the world in only two genders and having a non-heteronomous sexual orientation. Looking for the inclusion of the LGBTQ+ rights in the feminist agenda means transforming numerable prejudices, among women themselves, who do not see transgender women as being real women because they were biologically born a male; however, these women are the most prone to discrimination and hateful rhetoric:

In today's current political climate, both nationally and internationally, it is painfully obvious that the LGBTQ+ community and women are not treated as equals towards their straight, male counterparts. Both women and the LGBTQ+ community have an obligation to fight for their rights. Their right to not be discriminated against based on their gender and/or their sexual orientation; their right to not be harassed in their everyday lives; and their right to live a peaceful, happy lifestyle in whatever way they choose, without prying eyes judging their every breath and move. (Grain 2017: 1)

By the late decades of the twentieth century, the magnitude of the ecological crisis confronted the ideological and epistemological androcentric and anthropocentric frameworks that have oriented

modern society, which disregard nature as the essential milieu for all life. This *anthropocentric* thinking conceives growth, social progress, and human creativity beginning and ending with the individual (Shea 1998). A global neoliberal market economy imposed individual consumerism that demands more and more natural resources and land, which in turns expels local people from their territories and generate unwelcome migrations, particularly from the Southern hemisphere. As Vandana Shiva (2001) has stated: Globalization is causing new slavery, new holocausts, new apartheid. It is a war against nature, women, children, and the poor. *Ecofeminism* has thus become a powerful current of thought and a social movement that links environmentalism and feminism, revealing that the subordination of women to men and the exercise of patriarchal power are also an expression of the submission of life to the predatory demands of accumulation and exploitation of nature (Herrero 2013). *Decolonial feminisms* or *feminisms from the South* have also emerged across the planet denouncing the strong relation between capitalism and colonialism, which has increased women's oppressive experiences around the globe and their aspirations for living with dignity (Gargallo 2012; Herrero 2012; Wylie 2001). These feminisms will be more widely described in the next section.

We agree with Castells (1998) that this *polyphony and multiplicity of feminist identities* should not be considered as a source of weakness but of strength, considering the emergence of global networks and diverse dynamics of social conflicts and power struggles to question patriarchy in its very diverse manifestations: homophobia, undervaluation of girls and women, exploitation of nature, and the apology for authoritarianism and militarism. All these discussions and diversity of perspectives have fed the feminist movement, which finally achieved that the United Nations General Assembly declared the first World Conference on Women by 1975 and the Decade for Women's rights from 1976 to 1985. On 18 December 1979, the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW) was adopted by the United

Nations. The Fourth World Conference on Women, held in Beijing in September 1995, despite the great diversity and different global provenance of participants, shared a single goal: gender equity and the empowerment of all women, everywhere.

More recently, expressions of diverse polyphonic voices from the South were articulated in the *III World Conference against Racism* organized in South Africa in 2001; the *United Nations Declaration of Human Rights of Indigenous Peoples*, adopted in 2007; and the *United Nations Declaration on the Rights of Peasants and Other People Working in Rural Areas*, approved in 2018. All contains special articles on gender equity rights as a result of long consultations within and among very diverse social movements and organizations.

Feminisms from the South: Anti-racist and Decolonial Resistances³

Afro-descendant women face double discrimination because of our race and gender, and additional discrimination because of poverty. (Charo Mina-Rojas 2018: 1)⁴

In the community assemblies, we say that we agree to declare our territories free of transnational corporations. In the same way, we also want these same territories to declare themselves free of violence against women. (Aura Lolita Chávez Ixcaqui 2014: 19)⁵

The structure of modern society and its worldview became strongly influenced by the European colonial project since the sixteenth century: a global hegemonic structure of power put in place by the conquest of territories overseas, articulating race and labor, land and people on the basis of material

³Because of our personal experience and knowledge, we limit ourselves here to some approaches from Latin America. The rich contributions to feminisms from the South, from Islamic and Secular Arabic women's movements, as well as from other non-European cultures from Africa, Asia, or the Pacific, deserve a further dialogue with authors from these contexts.

⁴Our own translation to English from Spanish.

⁵Our own translation to English from Spanish.

gains (Escobar 2007; Walsh 2012). As Escobar (1998) explained, concepts like “poverty,” “Third World,” or “underdevelopment” were coined to globally promote the First World’s capitalist model of development, imposing extractive and monocultivation economies, with extended costly credits to Southern countries. This has ended up in the displacement and the loss of the territories of Indigenous, Mestizo Peasant, and Afro-descendant rural communities, with devastating impact on women and children.

Coloniality, the dark face of modernity, has denied and made invisible epistemic rationalities and cosmovisions different from those of European White men origin (coloniality of knowledge), dehumanizing women and men from non-European populations based on the reason-racial rationality of “civilized individuals” (coloniality of being) (Walsh 2008). Many ancient worldviews and epistemologies understood the feminine and masculine as complementary; the masculine and feminine duality-unit was an integral part of the creation of the cosmos, of its (re) generation, and maintenance (Marcos 2018). Diverse cosmogonies recognize not only gods but goddesses such as *Pacha Mama* or *Mother Earth*, source of life and wisdom for Indigenous peoples (Green 2011), or *Lemanjá* or *Yemanyá*, the mother of all Orishas (divinities or gods), the womb from which all the world’s oceans were born for peoples of the African diaspora (Allegue 2020; Simpson-Wilkey et al. 2020). However, the European conquest and colonization of territories overseas was expanded under the patriarchy’s umbrella of the Christian monotheistic culture, which has been detrimental to the subjectivities of the diverse Indigenous and African origin people across all Latin America.

Undermining the feminine in non-European cosmogonies increased patriarchal traditions under colonialist domination up to today. Christian colonizers declared these cosmogonies superstitious and inferior; they were violently banned, some of them giving rise to what Paredes (2014) call a patriarchal junction, the crossing between ancestral patriarchal practices and Western male-centered culture. Today, women’s from Indigenous, Afro-descendant, and Mestizo

Peasant origin have called the attention to the complexity of being doubly oppressed: by the dominant colonial culture and by their own traditions. As the Maya leader woman Lorena Cabnal expressed: “*I was told that most of us Indigenous peoples lived in harmony; then I begin looking at my own world and recognized forms of machismo, what I later called the original ancestral patriarchy*” (in Giménez and Bravo 2017: 1).

Feminisms from the South (decolonial, popular, community or Abya Yala⁶ feminisms) (Espinosa et al. 2013; Gargallo 2012) emerge as a political and ethical project, a new epistemological and political pathway, developed from, to, and through women from the South. They are diverse projects that propose the deconstruction of the current colonial/modern project, where race has been inseparably linked to a hierarchical division of the world, subjugating racialized women’s bodies, labor, thoughts, knowledge, and rights. They are made up of diverse efforts to subvert historical determinisms, discover new roads for humanity, and tell other stories. They bring to light racialized women’s voices, wisdom, and know-how that for years have been made invisible and silenced by hegemonic male colonialist discourses.

As Lugones (2008) explains, an *intersectionality* perspective of gender, race, and class is needed to interpret the complex realities that Latin American women from Indigenous, Afro-descendant, and Peasant Mestizo origin endure. This means recovering their own selves, knowledges, mysticism, and stories from which they were dispossessed, as well as re-encountering and re-signifying their own bodies. Bodies that cannot be understood without the access to the territory, the water, and land that give them life. As expressed by the Maya feminist Lorena Cabnal:

I assume the recovery of my expropriated body for the generation of life, joy, vitality, pleasures, and the construction of a liberating knowledge for my own decision making. However, this personal power

⁶Abya Yala is the name given to Latin America by the Gunadule people, who inhabit the region between Panama and Colombia since precolonial times. It means land in full maturity or land of vital blood.

needs to go along with the defense of my land territory, because I cannot conceive my own woman's body without a space on earth that dignifies my existence and promotes my life in fullness. (Cabnal & ACSUR- Las Segovias 2010a, p. 23)⁷

Feminisms from the South unfold from the voices of marginalized women in Latin America, who take a different stand-up from modern urban "Western" middle/upper class feminisms, which have had difficulties in acknowledging the complex struggle that diverse Afro-descendent, Indigenous, or Mestizo Peasant women undergo: for one side, the anti-imperial and anti-colonial resistance they entail collectively against territorial displacement, labor exploitation, and extractive economies. For the other side, creating organizational and creative strategies to change patriarchal beliefs and practices at the interior of their own families and communities to transform authoritarian and violent patterns and behaviors of leaders, fathers, partners, and other male members of their communities, who are oppressed as well (Gargallo 2012; Paredes 2014).

Transforming Women's Oppressive Realities: Some Experiences from the Ground

The following are a few examples from the many diverse initiatives that describe how feminisms from the South in Latin America are growing by creating alternative historical projects to build solidarity networks and actions to radically transforming existing structures, institutions, and power relations, towards what Catherine Walsh calls, the depatriarchalization, decolonization, and demercantilization of life, nature, and territories (Walsh 2013).

The Rural Women Workers Movement emerged in 2004, as a political faction at the interior of the Landless Workers' Movement (*Movimento dos Trabalhadores Sem Terra*, MST) in Brazil, to bring to light the silences but also the voices of rural women. Since the creation

of the MST in 1986, the place of peasant and working women within the movement was not noticeable. They had to rethink themselves and consolidate their participation, both for themselves and for their peers, to become visible as *political subjects*. As the leader Etelvina Masioli said, "*It cannot be accepted that the same hand that plants agroecology and propose an equal society, it is the same hand that hits, mistreats, assaults, and represses a woman*" (in Longo 2015: 166). The MST, through women's leadership, has thus become a **peasant feminism**, a decolonial project against patriarchy and the commodification of the earth and life. It has been inspiring the construction of community and solidarity feminisms around the world.

A similar purpose on building a peasant feminism can be found in the experience of the Association of Organized Women of Yolombó (AMOY) in Colombia. As Cárdenas (2013) describes, AMOY was born in 1995 in the midst of the Colombian armed conflict, oriented to protect rural women's human rights and territories; promote their autonomy, subsistence, and sustainability; support their visibility in political and communitarian spheres; and strength their resistance practices exercised in defense of their lives and their territories. Women meet in group and start together the recovery and reconstruction of their identities as peasant women. The collective work was a strategy for the construction of their autonomy in different aspects: productive, individual, family, and community, all interrelated and understood as a complex fabric of vital relationships.

Communitarian Indigenous feminisms can be appreciated in the initiatives of the *Aymara Women Creating Community* in Bolivia as well as the Xinka women of the *Association of Indigenous Women of Santa María* in the mountain of Xalapán, Guatemala. They shared the common effort of working for the recognition of their own oppressions and rebellions as Indigenous women but also in the defense of their ancestral territories, which are inhabited by women themselves (Cabnal 2010a, b; Guzmán 2015). These communitarian Indigenous feminisms aim to create, recreate, and mobilize concepts, reflections, and

⁷ Our own translation to English from Spanish.

proposals emphasizing solidarity. They are diverse and plural experiences committed to transform Indigenous women's oppressive history and reality because of ancestral patriarchal beliefs crossed with Western colonial patriarchy and racism.

The African diaspora feminisms emphasize the particularities of black women's own situated struggles, considering the devastating historical consequences of slavery, reproduced up to today by racism, poverty, and violence. From the intersectionality perspective, the dimensions of race, gender, and class are inseparable identity components in their different experiences; these dimensions highlight the matrix of domination that affects black women's lives in a differentiated way (Jabardo 2012). For Betty Lozano Lerma (2015), feminism cannot be one because women are diverse. She has contributed to the consolidation of a black, popular, and decolonial feminist project, from which to make visible the discrimination of black women and the claim for their rights. Lozano Lerma (2010) highlights how various black women construct subversive proposals of the social order that oppresses them in different ways, due to their racialized condition and their poverty. Cogollo, Flórez and Nández (2004) illustrate, for example, the Afro-Caribbean women's struggle to strengthen their rights and participation in private and public spaces, while questioning the unequal relations with their male partners that cause them suffering and unhappiness. Nonetheless, they invite not to ignore the complex psychological vulnerability and economic oppression that Afro men from their own communities endure as well. Francia Márquez (2018), as a renown environmental activist, human rights defender, and leader of the Afro and artisanal mining communities from the Colombian Pacific region, emphasizes how a feminist position must be interwoven with the defense and care of local communities' lands and the environment. This means making visible and strengthening the fundamental role of women in the care of life in all its manifestations. For Márquez (2019), patriarchy together with racism and capitalism have been the forms of oppression that are destroying the planet, putting it at high

risk and threatening the lives of women and girls in multiple ways.

The above are just a few examples of the large diversity of women's voices from Latin America, which have been contributing to enhance the feminisms from the South perspective as a plural and shared creation in solidarity, looking forward to build other possibilities of being and living differently from the modern individualistic and consumerist society. They are being configured as a political, epistemic, ontological, pedagogical, and intercultural ethical project, opening new avenues towards other possible knowledges, views, languages, and ways of thinking; other possibilities of living with the others and nature.

Some Conclusions – The Feminist and Humanistic Quest: Transforming Exploitive Relations Between People and with Nature

Despite so many historical, geographical, and political differences, the feminist movement has been creating common routes, although shaped from different women's paths. As Freire expressed: "I live history as a time of possibility and not as following a determined existence" (2012: 98–99). Possibility understood as openness to transform oppressed situations, to change a reality conceived as immutable, to look at dreams, and create together a utopia. Since its naissance, feminist thought has strongly worked to demystify and denaturalize the ways of being, doing, and feeling, which have determined the way women are understood and understand themselves through history. In this way, feminism, in its different expressions, has questioned the role that men and women have occupied in society, supported by an alleged biological determinism that undervalues women. It has been opening paths towards the construction of other possibilities of being, other ways in which women can be recognized and recognize themselves.

Feminisms from the South take shape from the voice of marginalized and racialized women in Latin American, asking questions to the academic world that otherwise would not have been asked.

They are a quest to advance women's human rights as part of the struggle against racism, ethnocide, and the domination and subjugation of entire populations, who have been considered primitive and inferior by different economic powers. It also means the defense of the territories, water sources, and ecosystems in which women recreate life, recognizing nature rights as well. A plural and solidarity feminism cannot be built without considering the human rights of impoverished women from the South to health, education, and political participation. This means to all of us to support the defense of their territories and ecosystems from predatory economies, the territories in which they build life with their communities.

Fiction · Aesthetic experience · Myths · Fantasms · Eduardo Coutinho · Creativity

Definition

This entry proposes the understanding of fiction as a pervasive dimension of psychic reality, that is, a reality constructed by a unique subjectivity that

creatively transforms the I-other-world relationships through an affective-cognitive meaning construction gestated in the dialogical intimacy of the relationship with cultural multivoiced arena. Based on literary experiences, the proposed discussion highlights the ethical and aesthetic dimensions of fiction in culture based on Gadamer's hermeneutics and Richard Rorty's considerations on imagination and literature. In the universe of fiction theorization and psychological-subjective experience, Ernest Boesch's contributions about the transformative dynamics between individual and culture are emphasized through the affective dimension that acts on the relationship between collective myths and individual fantasms. Finally, as an interpretative exercise of the proposed construction of fiction, the speech of Alessandra, a character from the documentary *Edifício Master* (directed by Eduardo Coutinho), is presented as a way to examine the fiction inherent to the construction of metaphors and meanings for the alterity of life.

There are many emblematic expressions in contemporary Western cultures in which truth has become increasingly based on passionate collective consensus, rather than its factual verification or argumentative dynamics. Post-truths, fake news, and denialism are vivid examples of version reconstructions of actual social facts. In the actual Western democratic crises – intensified by media customization and the affective power of virtual societies with their algorithms – bubbles have become a landscape for meaning constructions predominantly based on validation by peers and not by the tension toward their possible opposites that could trigger transformative processes in culture (Pinheiro 2019; Tateo 2018; Lakoff and Guill 2018). In the context of mass behavior, as shown by the modern and contemporary history of the Western world, fictional modes of the reconstruction of reality can take on destructive guises when their dynamics serve the reduction of human diversity.

In this cultural landscape, a reinvestment in possible meanings and understandings about the fictional dimension of individual and collective lives is reassigned as a major task for the humanities, given the special interpretative value of fiction in the processes that subjectivize reality, as

well as its ethical impasses in the universe of human relations. It becomes obvious, however, that in the field of opposite meanings for fiction, there is no place for a unique sense of truth. Far from it, the fiction dimension – ever since its emergence in literature and up until its actual insertion into the relationship between individual and culture – expands and diversifies the concepts of reality, that is, it amplifies the treatment of human “truths.” This is because the latter are subjected to the multiplicity of meaning potential and nebulosity in human truths that has been culturally forming them, as well as the ambivalences of their actors toward such possible senses of truth (Pinheiro *in press*). In the words of Argentinian writer and essayist, Juan José Saer, author of *O enteado* (2002):

By moving towards the unverifiable, fiction infinitely multiplies treatment possibilities. It does not deny an alleged objective reality; on the contrary, it submerges in its own turbulence, showing disdain for the naive attitude of pretending to know in advance which way reality will fall. It is not hesitation before this or that truth ethic, but the pursuit of a somewhat less rudimentary ethic. (Saer 2012, p. 3)¹

Thus, the author describes fiction not as an exercise in reality transfiguration but, above all, as a dimension that articulates with the field of the possible, the invisible, with that which is in the larvae phase or, still, with the potentiality for multiplicity implied in the emergence of whatever erupts as truth. Fiction would thus contemplate not the false, but the multiplicity implied in the illusions of the one transparent and all-encompassing truth.

Therefore, this entry focuses on fiction as a register inherent to psychic reality, that is, a reality constructed by a unique subjectivity (Bakhtin

1999) that creatively transforms the I-other-world relationships (Simão 2010; Boesch 1991), through an affective meaning construction elaborated through the dialogical intimacy of the relationship with cultural multivoiced arena (Pinheiro *in press*; Simão *in press*). In this perspective, the possible is not seen only as a result of life’s flux eventicity in the irreversible time. The possible is encompassed by an active construction raised from a potentiality inherent to the creative force of fiction, this inherent register of psyche.

To deal with this proposition, this entry will be subdivided into three parts. At first, the matter of fiction will be viewed under Richard Rorty’s perspective (1999); for the specific purposes of this entry, we will stick to his specific contribution to the creative power of literature in the relationship between culture and the individual. In this section, some of Gadamer’s (1989) propositions about aesthetic experiences and experiences in general will be presented. Taking this path, we seek to shed light on the extraordinary potentiality that life’s normativity can harbor. After this aesthetic and philosophical discussion, the focus will shift to the sphere of psychological theorizing using the reflections of Ernest Boesch (1984, 1991, 1993) about the relations between myths and fantasms in the affective regulation of the potential field of human action. As proposed in the present encyclopedia’s theme, the proposed approach of fiction is an approach of human construction of possible, as a landmark not only of the non-determinacy principle of subjectivity but of its creative-transformative way of constructing realities. Finally, in order to encompass the subjective experience in a living, empirical datum, we will call into discussion the speech of Alessandra, a character interviewed by the Brazilian documentary filmmaker Eduardo Coutinho, in the movie *Edifício Master* (2002). The film presents the narratives of the residents of this Copacabana building, located in a neighborhood of the state of Rio de Janeiro, Brazil, about their dreams, challenges, and daily lives. It is by examining the art of Coutinho’s encounters that we will shed light, in this chapter, on possible meanings for fiction and their ways to remain current in the dynamics of human action.

¹Original text: Ao ir em direção ao não verificável, a ficção multiplica ao infinito as possibilidades de tratamento. Não nega uma suposta realidade objetiva, ao contrário, submerge-se em sua turbulência, desdenhando a atitude ingênua que consiste em pretender saber de antemão como essa realidade se conforma. Não é uma claudicação ante tal ou qual ética da verdade, mas sim a busca de uma ética um pouco menos rudimentar (2012, p. 3).

Aesthetic-Philosophical Assumptions About Fiction: Contributions by Rorty and Gadamer

The intention in bringing Rorty's neopragmatist perspective and Gadamer's hermeneutics into dialogue is to stimulate reflection on the ethical and aesthetic dimensions that are implicated in the question of fiction in human experience. As mentioned before, the possible in human experience is thought as a construction related to the pervasive fictionalization of reality inherent to human psychological open dynamics, and, in this sense, it can lead to different ways transforming I-other-world relationships in individual and collective levels.

In this particular sense of bringing together Rorty and Gadamer, what is proposed here is to identify points of possible dialogue between both philosophies, points that may signify a *frontier/border* dimension to advance in this reflexive exercise between the conceptual grammars of these two thinkers who, despite being anti-essentialist, produced markedly distinct orientations².

As presented earlier, if Saer, author and essayist (2012), proposes fiction as an amplification of reality, Rorty (2010), through the allegory of literature, makes an important contribution about the role of the latter and, consequently, of imaginative fiction in the ethical horizon of human relations.

Anti-essentialism is a fundamental milestone of Rorty's philosophical landscape. For the author of *Contingency, Irony, and Solidarity* (1999), the truth is not before man to be contemplated, since it does not exist in advance of linguistic activity. In this perspective, what we believe to be true is understood as a consensus effect of a specific community, based on language games, and therefore always contingent and historically dated. The history of intellectual evolution, the production of

knowledge, would not be considered as a growing understanding of "real facts," but rather as the history of metaphors and their process of becoming better and more useful in answering questions inherent to social practices. The ideal of making a transparent description or even a realistic portrait of the inner truth/essence of anything is here thought of as a fiction that allows the realization of specific and contingent human purposes. A result of such reasoning, the knowledge production method would be thought of in terms of its instrumental value in producing a human community amplified in its sensitivity concerning the needs and the dignity of others, an expansion of the "concept of us" (ethical value thought of as the motor of scientific production). According to Rorty, the work of the researcher consists of:

This sort of philosophy does not work piece by piece, analyzing concept after concept, or testing thesis after thesis. Rather, it works holistically and pragmatically. It says things like "try thinking of it this way" – or more specifically, "try to ignore the apparently futile traditional questions by substituting the following new and possibly interesting questions." (Rorty 1993, p.9)

The aforementioned highlights the creative power of language on which Rorty focuses. For this thinker, vocabulary (Wittgenstein 2009) would be an instrument capable of doing something that could not be thought of "prior to the development of a particular set of descriptions, those which he himself helps to provide" (1993, p. 25). In this context, the philosopher discusses the relevance of the ironist tradition that recognizes the uncertainty of its own vocabulary, since it was produced by other inherited vocabularies. The ironist attitude also does not believe that its own vocabulary is the key to answering all questions.

That's the path in which imagination is fundamental to the neopragmatical Rortian perspective, as it would be key to amplifying our ability to perceive the suffering of others and to build an effective register for solidarity, for the recognition of the dignity of the suffering of others as well as ours. For the author, what makes us similar to each other as humans is the propensity to pain and humiliation. This unique propensity of the

² Although there are many aspects of discussion about the convergences and divergences between the perspectives of Rorty and Gadamer, let us not dwell here on approaching them all. For an understanding of the background and implications of this discussion, see, for example, Bowie (2004).

human condition is the only one Rorty recognizes as universal, thus marking the anchor of the ethical, nonrelativistic attentions of liberal and democratic communities.

Literature, according to Rorty, would be able to amplify, via the reader's imagination, people's sensitivity to particular details regarding the pain and humiliation of the other, of the non-I, including the non-I existent in me, in the sense of my own pain and humiliation that I don't recognize as part of me. Under this light, solidarity would not be fully attained by abstract theories, rationalizations, or concepts. Far from it, literary fiction would be the main path on the road to expand the possibilities of our empathic identification, understood as a form of participatory emotion. Novels, ethnography, and documentaries would be effective means for transforming life forms. As an important psychological aspect, Rorty states:

The only thing which can let a human being combine altruism and joy, the only thing that can make either heroic action and splendid speech possible, is some very specific chain of associations with some very idiosyncratic memories. (1993, p.153)

In this sense, Rorty recognized that, in the aesthetic enjoyment of literature, the idiosyncrasy proper to the reader's private sphere of life would be triggered in the act of experiencing the otherness of the art, proper to the public domain. The relationship between such experience and the strong poet, who reconstructs his own autonomy in light of a new vocabulary, would instigate new forms of solidarity by lending his uniqueness as an empathic attitude about the other's pain. The strong poet would make the blind spot given to them by chance a field of attunement to the other's pain. In performing his new vocabulary in order to avoid cruelty, the strong poet would enhance his field of action and amplify the concept of "us."

Rorty does not see literature as the object of a specifically aesthetic reflection but, above all, an ethical one. However, the philosopher leaves important clues for the reflection on the meaning of his aesthetic experience and the fictional role of the reader, as the one who imaginatively recreates the work of art. It is in this sense that Gadamer's hermeneutics can be summoned, since he is a

contemporary author who sheds light on the vicissitudes of aesthetic experience.

In *The Ontology of the Work of Art and its Hermeneutic Significance*, Gadamer (1989) proposes that the aesthetic experience would be characterized by the logic of simultaneity. The discontinuity experienced in rapture – which undoes the differentiation borders between subject and object – is concomitant with the holistic, continuous whole of a subject who amplifies the register of his truth through the immersion in the lived experience. In his words: "Therefore, the viewer's ecstatic self-forgetfulness corresponds to his continuity with himself. It is precisely that in which he loses himself as a spectator that demands from him a continuity of meaning" (p. 186). Thus, the philosopher points out that, despite the traditional primacy of the rational concept of aesthetic representation in the Kantian tradition, it is imagination that expands human capacities, enhancing the free play of forces in the process of knowledge construction. Aesthetic experience would be a form of knowledge production neither inferior nor superior to the universe of abstractions but, above all, implied and instigative of the emergence of the novelty and the overdetermination of the possible.

The temporary disappearance of the border between reader and text, between audience and work of art, allows for the most transformative exception, at the same time tangled into in the usual ordinariness of everyday life, a silent opening to that which is not us and inside of us is makes itself said (Frayze-Pereira 2005). It would not be a transfiguration of reality, but of its own truth: "he who dreams, awakens." Inspired by Simmel, Gadamer (*ibid.*) characterizes the quality of the experience, as an aesthetic structure, as the grammar of adventure. It interrupts the usual movement of things, moving toward the uncertain, arresting commitments and conditions. This would be the path toward a wealthier return of the subject to the meaning of his/her life.

That which does not exist but is, above all, the world we live in, our own world. The configuration of transformation is not simply a transference to another world. It is certainly another world, closed in itself, in which the game is played (*ibid.*, p.167).

In the abovementioned quote, there is a provocation about that which does not exist and, paradoxically, it would be our own world. Using the metaphor of the game to understand the aesthetic experience, Gadamer draws attention to the fact that every game owns the player as if it was his/her only master. In the playful event, the rules and dispositions that constitute the game configure a way of losing oneself, of excluding any kind of subjective firmness. If gaming suspends the ends that guide the ordinariness of life through the sacred earnestness of playing the game, the game itself would never be a passive object, just as art is transformative of those who experience it.

It is never a magical, strange world, a rapture, a dream to which the actor, sculptor, or spectator is drawn, but always their own world, to which they most authentically refer when recognizing themselves more deeply in it (p.192).

The philosopher points out that if, on the one hand, there is this eclipse between subject and object of experience, on the other hand, it does not signify the creation of a separate, unreal world filled with sweet sounds. The idea here focuses on the construction of a surplus of vision (Bakhtin 1990) caused by the amplification of the polysemy and affectivity of the lived experience. If, on the one hand, the ordinariness of life is a sociocultural mesh that gives cadence, rhythm, a set of regularities proper to the collective circuit, on the other the intimacy of the fiction existent in aesthetic experience would be an inherent dimension to the impact of the ambiguity of the signs of experience. This process harbors a sort of distancing from the immediacy of performance toward the otherness of the voices that constitute the subject and participate in the expanded construction of meanings of the lived life, or, rather, the blind spot presented by chance (Rorty 1999).

The Theory of Symbolic Action and the Fiction of Each One of Us

Even when the intention of veracity is sincere and the narrated deeds are rigorously accurate - which is not always the case - the obstacle of the authenticity of the sources, the interpretative criteria, and the

turbulence of meaning characteristic to every verbal construction still remain. (Saer 2012)

According to Boesch's (1984) theory of symbolic action, culture is a field of action in which the world, objects, and contingencies are signified in a markedly personal way through an ambiguous and heterogeneous sign system. Semiotic channels of action – as is the case of conventionality and a number of diverse significant otherness aspects in the directing of messages – are a subjective extension of the individual, which participate in the transformative-creative dialectic in light of the disquieting and alteritarian objectivity of the nonself (Simão 2010). For instance, when children from middle school are asked to construct comic strips about a kid who studies at a school where nothing was forbidden, the unfamiliar situation of the task (the resistant object: a school where everything is possible) is recreated by using exactly the normativity of children's school quotidian. As an extension of author's self, an internalized conventionality otherness is subverted, in a microscale, among the course of action (Pinheiro and Simão [in preparation](#)).

In this sense, Boesch's theory – as interpreted by cultural semiotic constructivism (Simão 2010) – is discussed in the present entry once the affective basis of action, which regulates the construction of objectives, is systematized as the genesis of human potentiality in the face of the otherness of the world. In other words, the potentiality which creates action would be based on the uniqueness of each subject's biographical history and its modes of meaning making regarding the resistance of the objects of experience. In this perspective, we could say that subjective reality, the fiction inherent to the subjective condition, is a form of affectively oriented interpretation of the world supported by collective myths and individual fantasms.

According to Boesch (1991), myths “thematize obstacles that human beings face in their life, and ways of dealing with them” (p. 112). They are told to us by others. Myths are both constantly recreated and maintained by social actors for some purposes, at some periods, in some places, giving to the social actors an opportunity to fulfill prescribed social roles, allowing them feelings of self-accomplishment, self-enhancement, and self-realization, as

well as preventing them from other actions and feelings. To this extent, myths are alive and usually have a long life (Simão 2007). As in the comic strip task mentioned previously in this entry, when the participants were asked why in a school where nothing was forbidden they still integrated tests for the main character, most of the participants used to say that they couldn't get a good job, become a medical doctor, without the tests. Without school grades, one of the participants said, they would become "garbage collector," indicating a certain type of meritocratic myth of failure and success in their fantasmic-creative construction.

Literature has an important role in reconstructing such myths. Moreover, they are not structures above individuals nor below them, but they are born and develop in an intimate bidirectional process: myths are channeled by people just as much as they channel personal symbolic actions (Boesch 1991; Simão 2007). What Boesch (1991) calls "assimilation of a myth into fantasms" is a constructive process of assimilating the meanings of a myth into one's personal developmental structure. However, this assimilation depends on the possibility of articulation of mythical stories and themes (mythemes) to one's previous experiential bases, which form our values, aspirations, beliefs, fears, dreams, etc. (Boesch 1991). In other words, the assimilation of a myth into fantasm depends on the possibilities of integrating mythical contents into the previous affective-cognitive basis the person has already been constructing, which is also in constant transformation (Simão 2010). In this perspective, this would be where fiction and the possible rejoins in human experience. By being so assimilated in fantasms, myths become content of subjective experiences, unconsciously taking part of personal aspirations, values, and identity, this later understood as a result of a constant structuring process (Boesch 1991).

The fantasm alludes to the refractory uniqueness of reality, given in the process of signification of the individual constantly trying to grasp the future's uncertainty. If myths are a knowledge constructions about the world that give it order and meaning, these discursive structures are not assimilated without the abbreviations and

emphases given by the subject's historical and affective uniqueness. If, on the one hand, myths contain rules and justifications concerning I-other-world relationships, on the other, which myths will be selectively activated in the subject's experience is a process governed by the fantasm. Fantasms would also be a form of imagination that generates action patterns. Thus, fantasms form a kind of concrete, structured, momentary, and unique subjective web that is activated in the process of meaning construction in the face of the indeterminacy of the future. In this sense, fantasms could be thought as a fiction brought to reality from different possible imaginative paths.

In this sense, it is worth noting that both fantasms and myths are not in the position of the antithesis of truth, but are, above all, a grammar for other forms of meaning construction, given by a marker distanced from the traditional notion of rationality. In the classic article *The Sound of Violin* (Boesch 1993), the beauty of sound is understood as a metaphor for the bidirectional relationship between culture and the individual. There is a dynamic between subject and object that is never merely objective-instrumental, but also and especially subjective-functional. In the subject's tensions over activity, mastery would be a creative becoming where the nonself, represented by the alteritarian resistance of the object of experience, becomes an extension of the self. The active antagonism of the object, in this case the violin, can constitute a barrier that produces feelings of limited action potentials. To master it, intensive practices, eventual dropouts, or even the achievement of some utopia, while experiencing the suppression of the difference between self and nonself, all constitute a markedly ambivalent and uncertain course. The affective regulation of action participates in ways of overcoming ambivalence, also producing superordinate goals that are distant in time, but which command actions and allow their sustenance, as in the arduous task of becoming a violinist.

In short, affects in addition to their actual functionality are polyvalent, i.e., possess or point to various meanings not immediately relevant to the ongoing action. In this sense they are symbolic as well as "real." Yet, basically, the same is true to

object cognitions – each representation and concept has their extension connecting them to various other mental contents. Symbolism, it would appear then, is much a quality of affective as of cognitive schemas (Boesch 1984, p.179).

In the *Affective Schemata* paper, from which the above quotation was taken, Boesch emphasizes the affective polyvalence implied in the network of symbolically articulated meanings not only as quality of the object but as subjective and functional regulation acting in the course of action. In this sense, the symbolic web of meanings marks the cultural inheritance of the signs open system. The symbolic order is thus semiotically articulated from an affective-fantasmic point of view. In this sense, Boesch shows us, on the psychological horizon of potential fields of action that ambivalent affects, which act on fantasm patterns, constitute the perception of oneself as an actor, “this very little studied perception” (1984, p. 178). It would then be through the ways of dealing with the ambivalences implied in the object’s resistances that the subject’s affective and singular sense transforms the action’s objective sense. In this path, it would be from fantasmic-idiosyncratic fiction that possible realities would come to exist, as well as the alterity of reality that transforms the affective-semiotic bases of the fantasies.

As presented earlier in this entry, fiction, in terms of its psychological dimension, would imply recognition of the register inherent to psychic reality, that is, a reality constructed by the active and singular oneness that creatively transforms self-other-world relations (Simão 2010; Boesch 1991), through an affective semiosis gestated in the dialogical and fantasmic intimacy of the relationship with cultural otherness (Pinheiro *in press*).

Thus, three fundamental perspectives stand out for an understanding of the hermeneutic meaning of fiction proposed in the present text:

1. Fiction, proper to subjective experience, is not opposed to reality, but can be characterized by the complexification that amplifies objective sense.
2. In terms of the psyche, fiction alludes to the affective-semiotic register that acts in the

interpretation of the otherness of the world. Fantasms, in the Boeschian sense, can be read as historical-singular refractions, or even particular assimilations of myths that operate superordinate goals implied in the course of action.

3. As a creative dimension of the experience, fiction can be thought of in terms of the aesthetic dynamics that arrest/suspend the separation between subject and object, as well as of having its own duration temporality, implied in intensification of the ambiguity of the signs of experiences, thus transforming the mesh of everyday life.

Alessandra³: The Fiction of Her Own Self

This section is about a brief interpretative exercise on the fiction inherent to the psyche in the relations between individual and culture. As aforementioned, Alessandra, a character from the documentary *Edifício Master* (Coutinho et al. 2005), was chosen. Her speech and narrative were chosen not only for their uniqueness and enunciative frankness but also for the features that made Eduardo Coutinho’s cinema an art capsule of the exceptional vicissitudes of the meeting. His cinematic minimalism (Moreira Salles et al. 2002)⁴ rejected any visual appeal beyond the interviewee’s narrative, displaying it virtually unedited. For the director, the attitude of confinement and testimony interested in the other’s way of life was fundamental, often triggering the disruptive emergence of affection in the field of self-narrative. This makes his documentaries enrapturing experiences because of the extraordinary enunciation constructions that the common/average subject can harbor.

³Available in https://www.youtube.com/watch?v=VazEqtcIM_U (last access: November 4th, 2019).

⁴Expression used by João Moreira Salles to characterize Eduardo Coutinho’s style, in not resorting to images and aesthetic-cinematic resources beyond the interviewee’s first-person narrative. Lecture available at <https://www.youtube.com/watch?v=LCYKFscdLB0&t=986s> (last accessed 11/11/2019).

It should be noted here that the term “character” may sound strange when we talk about the documentary genre and the living lives that make up the film. Although it is not the purpose of this text to construct a reflection as a film critic, it can be said that the character would be something that does not exist prior to the meeting between the interviewee, the interviewer, and the camera. As Bakhtin addressed in *Aesthetics of Verbal Construction* (2006), the interdependencies and differentiations between author-person and author-creator, author and character, character and hero, the character, such as Alessandra, in Coutinho’s documentary, should be understood as the product of the encounter’s alterity and its potential surplus of vision that breaks expectations and surprises the interviewer-interviewed-spectator triad. Between the performativity of the statements elaborated in the first person and the game of responsivities produced by the copresence of Coutinho and his camera, a third dimension emerges from the infra-linguistic, affective, and communicative register that arises in the filmic production.

Alessandra begins her interview by stating that she was not allowed to properly live out her childhood. She would not have been a “normal child” because her space of freedom was surrounded by her father’s vigilant posture, only allowing her the homeschool journey. He wanted to protect her “from everyone.” So she tells of how she got pregnant at the age of 14. The father of her child was a man she “thought she was in love with.” She found out that something strange was happening to her body, from which she concluded the pregnancy. In Alessandra’s report, a vibrant and happy countenance emerges when she speaks about the birth of the daughter, Alexia Carolina. In the film sequence, the character speaks about her first time as a prostitute and the satisfaction of earning 1 month’s worth of a regular job salary on one single time with a client. She joyfully says that she spent all of the money on fast food at a mall with her daughter. She says that on that day she felt like “a child who got the toy she desired the most.”

At this point of the interview, a sign emerges that permeated different moments of her presence as a character in Coutinho’s documentary, namely,

courage. While on the one hand she says that she would no longer have the “courage to spend one hundred and fifty reais on Mc Donalds,” on the other hand she reports that she can only “bring up the courage” to work after drinking. Alessandra says that even when the customer is an interesting and intelligent man, she feels disgust at the moment of payment. Alessandra narrates the recurring humiliations that make, “contrary to what others may think,” prostitution money not easy at all. We hear the following answer to Coutinho’s question about her *joie de vivre*:

I do . . . I do like [life] but I expect to die at any moment. I already told my mother: when I die do not cry! Because I’ll be better off than everyone here, right? Because there are a lot of bad people here in this world. When I die I’ll be happy . . . I don’t want to die, no, I love my life, but I know I’ll stop suffering, I won’t have to work so hard, to wake up at seven in the morning. . . that would be great!

In this speech, death emerges as a possibility potentially imminent to life, in a form of consciousness that does not place it in a soothing future. Taking another route, Alessandra neutralizes the uncertainty surrounding the moment of death, through the fantasm of freedom as a landscape of the extinction of suffering and hard work, as well as of bad people. The prohibition of the mother’s tears is an image that evokes the maternal otherness as a witness of that liberation, where there should instead be grief and mourning. We may ask how the vulnerability faced in the professional activity articulates with the benevolent and liberating death, a sign that acts as a fantasmic shield against the fear of losing her life.

Subsequently, the director points out her “courage” to talk about her life in the interview, because of what her daughter might think if she came into contact with the material in the future. Alessandra replies:

It’s not courage. It’s normal, I think it is normal. I talked to her, I think it’s normal. People nowadays, in the world we live in, their minds are in the world of the years before Christ. It’s over, everything normal in the world. People are born of all sorts. Men with men and women with women, right [homosexuality]? There’s fifty women for each man. There are loads of things that shouldn’t be normal. People stealing from people, politicians stealing from people, thieves stealing from poor people, right? (. . .) People think it’s normal, so

why would my job be considered abnormal? Should someone come and stone me? That's why I really talk about it, in my neighborhood everyone knows [that she works as prostitute]!

Alessandra deconstructs the moral potentiality of the question about *courage*. Through a metonymic approach to the transfiguration of the normality of life in culture, both in the field of sexuality and in the universe of the common good, Alessandra claims her share of normalcy. The indeterminate and opposing cultural otherness is signified as backward/conservative, "[their minds being] in the world of the years before Christ."

The inquiry that involves the metaphor of stoning and injustice emerges in the same discursive construction. This elaboration presents possible clues about the mythical and fantasmic dimensions that act in the construction of her own placing in regard to her activity in prostitution. The ambivalence implied between pleasure and disgust involved in the gains of the job, as well as the ambiguity about the sense of normalcy, is thus questioned in a passionate elaboration. The art of the encounter with Coutinho seems to trigger the fiction of her own self as a becoming. The fantasies thus arise in this perspective recreation of existence, provoking meanings that enable the transformation of ambivalences in the relationship with the objects of experience. In this act of speech, more than giving a description or an answer to Coutinho's question, Alessandra reconstructs, with potential aesthetic contours, the familiar strangeness that participates in her way of life. At the end of the interview shown in the documentary, Coutinho tells her that she, in the pre-shoot stage, would have stated that she liked to lie. Here's a brief snippet of the interaction:

I am a huge liar, I tell lies and I think that for us to lie we have to believe! We have to believe the lie for the it to work! And I'm a huge liar. Huge! I even cry to believe my own lies. You know that **there are lies that I believe to be true?**

What did you lie about in today's conversation?

Aahhhh, I didn't lie at all. Yesterday I lied to them because I didn't want to come to this interview. I said: "I'm going out and so I don't know what time I'm going to get there."

Because I didn't want to come, I was scared. As soon as I left, I came back, because I didn't want to, I was afraid. But today I really forgot! It didn't even cross my mind that I had an interview. . . . **I didn't even remember.** But yesterday I lied, so you can see how truthful a liar I am (smiles). I tell lies but also the truth!

In this passage we find a curious apparently paradoxical enunciative formation: a truthful liar who tells lies but also the truth. As if she were the actress of her own script, Alessandra seems to speak of the fictional abilities of her lived life: "I even cry," making the lie an art of its truth, invested with an almost playful authenticity in her account, the sacred seriousness of the game, as Gadamer would say. This is the way in which Alessandra becomes the author of her own narrative, revising aesthetic-fantasmic fictions that undergo metaphorical and meaning constructions for the alterity of her own life.

Introduction

Imagine a group of 26 strangers who came together for a student competition centered

around solving a sustainability issue. It is a long competition, which means that the team will need to divide tasks strategically, stay engaged, focus long enough to actually learn something, and create something meaningful that will help them when they graduate. That is a rather tall order, but the Solar Team Eindhoven (STE) of the Eindhoven University of Technology (Eindhoven University of Technology-TU/e) actually pulled it off in the World Solar Challenge in Australia and made a solar-powered car while they were at it. What does it take to empower a team to perform at that high of a level with high engagement, good division of labor, and long term commitment? With so many business challenges and day-to-day tasks depending upon knowledge work and teamwork, the answer is priceless, and we propose that it is *flow*.

Flow

The concept of flow (colloquially called “being in the zone”) was first published widely in 1975 by psychologist Mihaly Csikszentmihályi, who initially defined the construct as “a holistic sensation that people feel when they act in total involvement” (Csikszentmihályi 1975, p. 36). Over the intervening decades, he and his colleagues published many works about how flow experiences are considered by individuals to be some of the most enjoyable, rewarding, meaningful, and engaging they have experienced, and typifies flow as involving automatic and effortless action coupled with intense focus. The flow experience can therefore be viewed as an optimal experience of intense involvement, focus, and satisfaction in the present moment, and one that according to research (e.g., Csikszentmihályi 1997) is involved with higher levels of performance, as well.

The Nine Elements of the Individual Flow Experience

Csikszentmihályi and colleagues (e.g., Csikszentmihályi 1997) conceptualized flow using nine elements that are all present when a person experiences flow (see below). Three of

these nine elements tend to be solely emergent/experiential and are hard to create or promote intentionally and attempting to evoke them often backfires. The other six elements are more amenable to being generated by the individual either internally or by using aspects of the environment, which are often considered the prerequisites for individual flow (cf. Csíkszentmihályi 2009; Van den Hout et al. 2018). The presence of these prerequisites increases the likelihood that flow occurs or augments the intensity of the flow experience. The distinction between elements of flow that are readily developed (a.k.a., prerequisites, antecedents, or preconditions) and elements that are purely emergent (a.k.a. experiential characteristics, facets, components, or indicators) is illustrated in Fig. 1.

The Prerequisites for Flow

There are six elements of the flow experience that are readily modified by the individual to increase the chances of a flow experience occurring during the execution of a task (there is never a guarantee; cf. Csíkszentmihályi 1997; Hektner et al. 2007). One of the main elements is *autotelicity*, which is about engaging in a given activity because it is intrinsically rewarding and worth doing for its own sake. This is one of the original core aspects of flow (Csíkszentmihályi 1975) and demonstrates the value of being judicious in selecting activities that are appropriate to the situation and that are a fit with the individual's interests and current state (Csíkszentmihályi 1997; Davis 2010; Van den Hout and Davis 2019). In addition to careful selection of activity, one can increase the probability of a flow experience by setting *clear, proximal goals* about which one can receive *clear, timely feedback*, both of which help the individual direct their efforts in *putting a high level of skill towards meeting a commensurately high challenge* (Abuhamdeh and Csíkszentmihályi 2009). This, too, represents a controllable element of the experience insofar as the individual can direct the level of effort they choose to put in, and can establish a challenging goal that is likewise motivating and can emphasize the intrinsically motivating aspects of the task (van den Hout and Davis 2019). This is not inconsistent with longstanding linear models of

the flow experience (e.g., Fig. 2), but fits even better with more recent research indicating that flow is more of a continuum (Davis 2010) and a discontinuous, complex process (Ceja and Navarro 2009, 2011; Hektner et al. 2007; Hetland et al. 2018).

Still, Fig. 2 can be used as a clue for selecting a challenge and skill level based upon the desired experience and determining a growth trajectory for the individual so that they can stay in the sweet spot where flow is most likely. As noted above, the task experience can vary significantly, which means that one is likely to cycle erratically between relaxation, control, arousal, and flow, with a goal of staying within the flow continuum as much as possible.

The fifth element of flow is a form of *complete concentration* that excludes all distractions. The full measure of one's thoughts, efforts, and attention is applied only to the current activity. One can train in this aspect of flow through a number of different exercises (e.g., meditation, breathing, visualization) so that one can readily switch to deep task focus. One can also remove possible distractions in the environment (e.g., telephone) or internally (e.g., releasing work pressure, stress, uncertainty, fear of failure) that could act as disruptors. It is critical to note, however, that deep focus is only one characteristic of flow, and is in no way sufficient to do anything more than increase the likelihood of flow occurring if the context, goals, feedback, etc., are likewise at optimal levels during an *autotelic* activity (cf. Csíkszentmihályi 1996).

The sixth element of flow is a *sense of control* over the task at hand, such that one *does not fear failure* (Jackson et al. 2008). It is not that failure is impossible in such a case, for the presence of a high level of challenge often implies the very real possibility of failure, but rather that one is focused on achieving the goal and confident that one has the wherewithal to succeed (Sawyer 2007). The opportunity to prepare (e.g., training, practice, analysis, positive self-talk) for the activity, and consequently reducing the fear of failure and increasing confidence, makes this element also a prerequisite of flow. This goes hand-in-glove not just with deep concentration and goals set, but also with autotelicity. When one is engaged in the action for the sake of the activity, one is less

Flow, Fig. 1 A conceptual equation of the individual flow experience

Flow, Fig. 2 Challenge skill balance required for flow (adapted from Massimini et al. 1987; Csíkszentmihályi 1997)

inclined to worry about failure precisely because the focus is on the activity.

The Experiential Characteristics of Flow

As these six prerequisites increase the chance of experiencing flow, it behooves one seeking an optimal experience to aim for these conditions in advance. One must be mindful, however, of the role of context (Davis 2010) and that not every element can be controlled. Rather, one puts in the maximum effort to increase the likelihood of flow and then allows the activity to proceed and permit flow to emerge. One of the main emergent elements is the *merging of action and awareness*, in which one's actions feel spontaneous and automatic even as one actually has control over the activity (Quinn 2005). Consistent with this is the *loss of reflective self-consciousness*, in which one loses sight of one's own role as an actor or agent in the situation, and likewise the *distorted sense of time* (either contracted or dilated), both of which tend to be byproducts of the deep absorption that occurs during flow (cf. Kihlstrom 2008; Tellegen and Atkinson 1974). Along with the seven prerequisites for flow, the emergence of these three experiential characteristics clearly signal that an individual flow experience has occurred.

The Benefits of Flow Experiences

Flow experiences are considered profound and tend to improve the individual's overall satisfaction with life (Nakamura and Csíkszentmihályi 2009). Flow also promotes persistence in the activities in which it occurs (cf. Shernoff et al. 2014; Amabile and Kramer 2007, 2011), and likewise a higher degree of creativity and increased self-efficacy (the belief in one's own ability) and development (Csíkszentmihályi and LeFevre 1989; Csíkszentmihályi 1997; Ilies et al. 2016; Asakawa 2010). As such, flow can play an integral role in maximizing people's potential. But human beings are social creatures, and the demands of the business world today are so complex that no single individual can solve the extant challenges. Thus, it is important to look at flow at dyadic (e.g., Snow 2010) and team levels (van den Hout and Davis 2019).

Team Flow

Before diving deeply into the complex workings of flow and interpersonal dynamics, it is important to provide a working definition of the terms "team" and "team dynamic." A *team* is "a small number of people with complementary skills who are committed to a common purpose, set of performance goals, and approach for which they hold themselves mutually accountable" (Katzenbach and Smith 1993, p. 112), and a *team dynamic* is the sum of all of the actions, processes, and changes that happen within a team, either holistically or among its members (Forsyth 2009). This collection of forces affects the team's behavior and performance and is created by any number of factors. Extrapolating flow to the team level, *team flow* is the shared experience in which all team members are completely involved in a collaboration towards a gratifying and challenging common task. During this moment of optimal collaboration, they perceive adequate abilities to cope with the challenging situation and they have the feeling that their collaboration runs smoothly and effortlessly and consistently makes progress (van den Hout et al. 2011; Van den Hout and Davis 2019).

This description shares aspects of Pels et al.'s (2018) definition of group flow, which they defined as:

[A] shared state of balance within a group as represented by (a) fluent, positive interactions within the group, (b) a high collective competence of the group, and (c) a collective state of mind of the group by means of positive relationships between group members, often resulting in optimal collective performance and creativity, and making group flow a positive collective experience. (p. 18)

The description of team flow above is also similar to Sawyer's (2007) definition of group flow, which is defined as "a peak experience, a group performing at its top level of ability" (p. 43), where he enumerated ten flow-enabling conditions.

Building upon Csíkszentmihályi's work on flow, the literature on team dynamics (e.g., Salas et al. 2008), and the pioneering work of several researchers on plural forms of flow (e.g., Snow 2010; Sawyer 2006), Van den Hout et al. (2019) defined team flow as a shared experience of flow during the execution of interdependent personal tasks in the interest of the team, originating from an optimized team dynamic. As shown in Fig. 3, this optimized team dynamic is defined by eleven elements that enable and indicate the experience of team flow, seven of which are mainly prerequisites (enablers) and four of which are primarily emergent/experiential characteristics (indicators).

The Eleven Elements of Team Flow

The Prerequisites of Team Flow

Team flow experiences often initialize through a *collective ambition*, which reflects a shared intrinsic motivation (analogous to autotelicity in individual flow) to form a team and take on a common task that is meaningful and consistent with the values of the team members. This could be something enjoyable, like a game of soccer, or something important like providing good care to a patient. In all cases, the collective ambition also includes a recognition of the uniqueness of each of the team's members and how that will contribute to fulfilling the goal, which is a crucial foundation for mutual trust and coordination of efforts.

If there is a collective ambition in a team, the team members often jointly derive one or more challenging *common goals* to achieve concrete/recognizable results. From this, the team members are able to create *aligned personal goals* that they find personally meaningful (and often match self-designed developmental goals) and that draw upon their unique skills and values. In so doing, team members are able to *integrate high skills*. To be able to experience flow during the execution of tasks, it is important that people have a stimulating challenge that requires them to apply high levels of personal qualities, skills, or competencies. The high challenge needs to preclude a guarantee of success without inducing anxiety, which reflects a healthy tension that demands focus and energy.

For each team member involved, in order to achieve this optimal integration of team members' forces, it must also be clear at any given time who is engaged in which tasks and how those efforts relate both to the other team members' activities and to the team's overarching goal(s). This requires feedback on one's own task, the sub-team's task (as relevant), the group's [coordinated] efforts, and the collaboration process. In order for this feedback to meet the requirements of being clear, constructive, and timely, the team needs *open communication* and *safety*. Each team member must feel physically, psychologically, and socially safe to perform their individual tasks and to respond to what the others are doing. To achieve this, unnecessary and unacceptable risks need to be eliminated while giving team members the ability to take smart risks that are commensurate with their skills. If everyone's abilities are respected and viewed as integral to the team's success, cogent critiques that proceed on that basis will necessarily be positive and constructive even as they maintain the requisite level of candor to be clear and timely. This allows for clear lines of accountability and for task-oriented coaching, which in turn promotes a sense of both individual responsibility and of *mutual commitment*. The latter promotes compliance with agreed-upon rules of conduct, safety measures, and maintenance of personal and team integrity. These seven prerequisites allow each individual team member to experience flow while

Flow, Fig. 3 A conceptual equation of the team flow experience

performing their personal task(s), which sets the stage for the team's experiencing a group-level of flow.

The Experiential Characteristics of Team Flow

Team flow is when all team members experience flow during the execution of their interdependent tasks, which gives the collaboration its own unique character. Just like flow, team flow is an optimal work experience, but it adds a social dimension. Collaboration is optimal when the following four characteristics are present: *a sense of unity* as if the team were one acting organism; *a sense of joint progress* as if building effortlessly upon each other, so that team members feel the synergy and are performing at a Gestalt level above the sum of their abilities; a sense of implicit *mutual trust* with the belief that the team's task will be accomplished successfully; and a *holistic focus* on the shared task. All team members perform their personal tasks with deep concentration and in harmony with the (higher) goal of the team.

The Team Flow Model

An integrated model of team flow is contained in Fig. 4, in which the connections between the seven prerequisites and four experiential characteristics are highlighted. Collective ambition, the red octagon, is a starting point and anchor point. The other six prerequisites of team flow reflect the direction in which the team members want to move together, the attributes of a positive and supportive work environment, and a clear and challenging task division. These conditions, when activated by the collective ambition, interact with each other to activate the four experiential characteristics to promote the emergence of team flow.

The Benefits of Team Flow Experiences

The description of the 11 elements of team flow already contains a number of possible benefits. Most people like it when there is a challenge, clarity, structure, things run smoothly, and they

are deployed on tasks at which they are skilled and for which they are intrinsically motivated. Receiving feedback from team members may be difficult at times, but if this is done positively and constructively, it also offers growth opportunities. Seen in this way, there are already quite a few benefits to be gained from the team flow experience itself (cf. Csíkszentmihályi and LeFevre 1989). In addition, studies have suggested that team flow leads to better team performance, more individual happiness, a more positive atmosphere (Van den Hout et al. 2019), and more creativity (Verhoeven 2018). Moreover, the shared experience of engaging in a meaningful and intrinsically motivating activity while serving a collective ambition strengthens the team experience and the affinity (in all forms) for the activity, which also increases the desire for the team to reconvene (Sawyer 2007; cf. Asakawa 2010; Csíkszentmihályi 1990; van den Hout et al. 2017). It remains important to remember, however, that flow is not a lasting experience and comes and goes over the course of the team's endeavors. As such, a team should endeavor to promote flow, but not to obsessive levels, as these can lead to burnout, tunnel vision, and excessive risk (cf. Schüller 2012; van den Hout and Davis 2019).

The Continuum from Individual Flow to Team Flow

While team flow arises from individual flow experiences, and the chance is greater if the prerequisites for individual task flow are created via the team flow prerequisites, there are many in-between levels of flow that occur during team activities that warrant analysis (van den Hout and Davis 2019):

- *Individual task flow*: Flow experienced during the execution of personal tasks for the team's purpose varying from microflow to deep flow (cf. Davis 2010).
- *Interactive flow*: Flow experienced during interactions with other team members while completing a task together. These interactions

Flow, Fig. 4 The Team Flow Model (adapted from van den Hout et al. 2011; van den Hout 2016)

emerge from the team dynamic, and during these interactions team members get “in sync” with each other. This is sometimes referred to as interactional synchrony or flow synchronization (cf. Snow 2010; Keith et al. 2014; Magyaródi and Oláh 2015; Walker 2010). For interactive flow to take place, each person involved in the interaction should experience individual task flow and the interaction should not directly involve all team members simultaneously.

- *Contagious flow*: Experiencing flow through contagion by other team members’ individual task flow experiences while completing a task together. This means team members are affected by the flow experiences of their fellows, increasing the intensity of their own flow experiences as they perform their individual tasks. Contagion is the reason team flow often starts with one team member’s individual flow experience igniting a fellow teammate’s, who in turn ignites another and so on until a tipping point is reached where the remaining team members “sync up” or “plug

in” to the flowing team dynamic (cf. Bakker 2005; Walker 2010).

- *Unit flow*: The experience of flow at the unit level (one hierarchical layer higher than the individual level). This means that the unit’s performance as an entity is functioning “in flow,” as when the collective awareness of all members in that performing unit are smoothly merging with their joint actions. At this moment, the unit is functioning at the peak of its abilities (cf. Sawyer’s group flow definition, 2003; Salanova et al.’s collective flow definition, 2014; Zumeta et al. 2016).

Notably, all of the experiences above occur during team flow and highlight how individuals can feel that they are given the space to perform their tasks autonomously while still maintaining a sense of connection with the team.

Sometimes the performance of a personal task readily rises to the collective level because of the tight link required between individuals’ tasks. Consider, for example, a rowing team or a healthcare team that performs a surgical

operation. Though individuals are performing separate tasks, the effect of every person's task has a clear and direct impact upon every other person's task and upon the collective performance. In other teams, the mutual link is less strong, such as in a home care team where the nurse goes out alone and the interaction with teammates is often not direct (and can even be turn-based) when providing care. Despite the cumulative nature of each person's work, the lack of real-time integration of the effects makes team flow more elusive.

Disruptors that Block Team Flow Experiences

In addition to looking at the factors that promote team flow, it is worthwhile also to review team flow inhibitors, such as negativity, politics, ambiguity, fear of failure, and insecurity (van den Hout et al. 2017). Corollary to the items above, there are four main categories of obstacles. Motivation is a major underpinning of flow, but is readily killed by laxity and bureaucracy, both which inhibit accountability, trust, and the freedom to take the requisite smart risks. As open communication and trust are essential to team flow, miscommunication, destructive criticism, personal conflict, and gratuitous negativity are inimical to the flow experience. Just as clear goals and timely feedback promote flow, a lack of clarity, external pressures, limited challenge, and limited feedback inhibit team flow. And, notably, anything that causes distraction is going to remove any possibility of flow emerging. The good news about these pitfalls, however, is that they are relatively easy to avoid and remedy with proper precautions, planning, and coaching.

Team Flow Catalyzes Unprecedented Possibilities in Challenge-Based Learning Environments

In today's practice, be it in schools, business, or daily life, intricate challenges are increasingly

appearing. To answer the call of these complexities, the education system (writ large, and including adult and professional education) has started developing *challenge-based learning environments* (CBLEs), which are crucibles for developing the intellectual and social skills to go after the toughest problems as a team (Nichols et al. 2016).

Needless to say, CBLE's would benefit significantly from ensuring that participants learn how to foster team flow. To achieve this, it is first of all important that all participants feel connected to each other and willing to commit to a collective ambition. This serves as the proverbial "stake in the ground" amidst the chaos and complexity and anchors the team to a point on the horizon.

From there, it is helpful to turn first to the experience of individual flow, looking at how each member of the collaboration can maintain their professional autonomy (freedom to act based on expertise) in a way that visibly and uniquely contributes to the team. Participants need to know how things are going and how they can contribute individually to take the next step together.

It is therefore important that everyone has the freedom to be themselves, act upon their personal values and views, and from there contribute to the cooperative effort. In this way, team flow can develop without the potential negative aspects that can arise in the emergence of a collective mind. Consider, for example, irrational decision-making by *groupthink* (Janis 1971) or exaggerating sentiments, showing impulsive behavior, or failing to reason, as described by Le Bon (1896) in *Psychologie des Foules*. Rather, professional autonomy must be balanced with alignment (see Fig. 5), in which the team uses the collective ambition as a foundation for establishing individuals' and units' challenging subgoals/milestones (Van den Hout 2016). What remains is to find a safe, efficient, and inspiring way of tuning into and receiving feedback on one another's work, and the literature on team workflows is rife with information about this (e.g., Hackman and Wageman 2005).

Flow, Fig. 5 The balance between alignment and professional autonomy (van den Hout and Davis 2019)

Once the group is aligned, it becomes necessary to create systems of accountability and methodologies for constructive feedback. This can be done, for example, on the basis of the following questions:

- Is there clarity about the expected team result?
- Is it possible for individual team members to join forces to form a dynamic/flexible performance unit?
- Is it possible for individual team members to experience individual flow during the performance of their personal task for the team?

If working groups are formed in the CBLE, not only must a joint assignment based on the collective ambition be formulated, but, as above, the instructor should work with the team to guide them towards developing the additional conditions that significantly increase the chance of team flow emerging and likewise keep disruptors out. As these conditions develop, the coach can focus on smoothing interactions and highlighting bottlenecks and disruptors as they emerge. A skilled facilitator can have the team working to counter these inhibitors, which can in turn strengthen the relationships among the team members.

By focusing on team flow, the team takes steps forward more quickly and participation in the

CBLE is likely to be experienced as useful, enjoyable, educational, and effective. If the desired solutions have not yet been achieved, the seed may have been planted to continue this in the future within future work environments or during subsequent participation in other CBLEs.

The success of the team flow model and ideas around it lies in its simplicity, its focus on the core ambitions, and its roots in positivity. The model has now been proven effective within healthcare organizations, IT companies, research and development institutions, construction companies, and educational institutions (van den Hout 2016; van den Hout and Davis 2019). In order for teams to experience team flow, it is the responsibility of organization leaders to ensure that the elements from the team flow model can be present for each team. They should therefore not bother the teams too much with unnecessary procedures, meetings, and policies, but rather provide the resources and freedom for them to be self-determining. Likewise, an important role for leaders is supporting teams' collective ambitions and challenging team goals (results) that fit the overarching values of the organization, particularly with the provision of personnel and resources. Hard as it may seem to some, it is actually incumbent upon leaders to provide these resources and then step back and leave the teams to their flow and the excellence it promotes.

The Eindhoven Solar Team has already become the world champion four times, and members of the original team are now bringing the first solar car, called the Lightyear One, to the market. They serve as a prime example for how a challenging collective ambition can be turned into a reality through team flow, and thence to solving problems of global proportions.

Forecasting

Roberto Poli

Department of Sociology and Social Research,
University of Trento, Trento, Italy

Abstract

Forecasting consists in the analysis of data and their future extrapolation. Forecasted events result from different types of formal models analyzing data on trends. Two fundamental assumptions governing forecasting models are the adoption of extreme time windows and the principle of continuity. Megatrends are forecasts *on steroids*. They refer to major transformations that influence many other changes, profoundly changing social forms and mechanisms and impacting on different economic sectors.

Consequence assessment

Introduction

Forecasting consists in the analysis of data and their future extrapolation. For a lively and non-technical introduction to the joy of statistics, to be recommended is the recent work by Spiegelhalter (2019).

Forecasted events result from different types of formal models analyzing data on trends – from the trend of inflation to changes in GDP, from the unemployment rate to climate change. Like all other models, forecasting models are based on some fundamental assumptions which condition their validity. Two typical areas in which forecasting models are carried out are econometrics and climate change.

Perhaps the most obvious limitation of econometric forecasts is that they work for *short time windows*: 6 months, 1 year, 2 years, etc., at even 3 years no one takes them seriously any longer. Unlike econometric forecasts, climate change forecasts adopt long, if not very long, windows, close to or longer than 100 years; this is because they require long time frames to separate the signal from the noise – that is, to distinguish the background trends from accidental and momentary changes. The second fundamental assumption underlying forecasting models is what I call the *principle of continuity*: the idea that the system considered will continue to work roughly as it has worked thus far (Poli 2019). This is an extremely reasonable assumption. If someone were to say that next year Italy's GDP will increase by 8%, we would all burst into laughter – or tears. Looking at how Italy works, the ruling and entrepreneurial classes, and the bureaucracy that cages the country, one is forced to admit that the idea that the Italian GDP can grow significantly is unrealistic at the moment. Continuity in the case of climate change models is provided by the constancy of the laws of physics.

Econometric and climate change models adopt extreme time windows – either very short or very long ones – and are based on their own principle of continuity. In both cases, the technical and scientific community is firmly in favor of them. So, what is wrong with these models? Nothing. Both are serious, robust and firmly anchored in sophisticated scientific and methodological knowledge. The problem is that we might also be interested in intermediate time windows (of 10, 30, or 50 years) and in discontinuities, surprises, and new circumstances.

With the obvious exception of demographic models – which also work for intermediate time windows and adopt their own continuity principle – forecasting models simply do not work with intermediate windows and with respect to changes. It could also be added that forecasting models do not work even with predominantly qualitative data or when the information available is not reliable (this happens with economic data much more often than people think, and it is no coincidence that such data

must be constantly reviewed). When we are dealing with intermediate windows and changes (but also with qualitative data or spurious information), we must necessarily adopt a different perspective. This is where the transition from forecasting to foresight takes place (see the entry ► “Foresight”).

Before proceeding, I should rapidly comment on the concept of time window (Poli 2019). The distinction among short (0–5 years), intermediate (10–50 years), and long (100 years and more) time windows is obviously vague and incomplete. It only serves as an initial orientation and does not help us with cases not explicitly mentioned. Is an 8-year window short or intermediate? The point is that the nature of the window depends not only on the technical properties of the model but also (and above all) on what we are observing. If we talk about mobile phones, 5 years is comparable to a geological age; if we are talking about changes in values, we must consider at least one or two generations. In any case, what is needed by futurists is a window long enough to bring out significant variations. This is the real intermediate window. A shorter one fails to detect the changes underway, a longer one overlaps and risks confusing different cycles of change. The exact specification of the time depth of the window depends essentially on the system under observation and the topic under discussion.

Megatrends and Related Concepts

Megatrends (occasionally known as macro trends or global trends) concern a series of changes that have been in progress for many years – typically for decades – and that are likely to last for a long time. Megatrends are forecasts *on steroids*. Megatrends have to do with major transformations that influence many other changes, profoundly altering social forms and mechanisms and impacting on diverse economic sectors. The term “megatrend” was introduced by Naisbitt in the 1980s. Since then, the term has been used in many senses, ranging from the journalistic acceptance of Naisbitt to the more rigorous one of Smil (Naisbitt 1982; Smil 2008).

Recent developments suggest different ways to construe the field of megatrends. While Gaub distinguishes between megatrends and triggers, Poli distinguishes megatrends from explorations (Espas – European Strategy and Policy Analysis System 2019; Poli 2019). The difference between megatrends and triggers depends on their velocity: megatrends concern changes proceeding at a slow pace, while triggers generate much faster, even sudden, changes. On the other hand, the main difference between megatrends and explorations is that the fundamental variables of the former are fixed, while those of the latter are open and oscillating. Put otherwise, megatrends have visible endpoints, while explorations may result in widely different outcomes.

Like megatrends, both triggers and explorations also involve coordinated series of changes. The difference is that these are developments with results that are still open and anything but predictable. Consequently, there is room for maneuver: our decisions and actions can divert the underlying processes in different directions. While it is almost impossible to change a megatrend unless in exceptional circumstances, explorations are much more exposed to interfering factors. Two examples are the new Silk Road project (aka the Belt and Road Initiative) and the labor market (Poli 2019).

However different they may be, the two proposals by Gaub and Poli evidence the need to develop a more nuanced understanding of megatrends and their accompanying phenomena.

With reference to the four layers of Futures Studies presented in the entry “► Foresight,” megatrends and explorations correspond respectively to forecasting and foresight, albeit *on steroids*. I refer to that entry for the main differences between forecasting/megatrend, on the one hand, and foresight/exploration on the other. The three most significant aspects are the following: both classifications refer to models; the difference between the first and the second group is sharp (i.e., no smooth transition exists between forecasting/megatrend models and foresight/exploration models); and the former group is based on rote iterations of past patterns, while the second group includes novelties and surprises.

Megatrends are so deeply embedded in the overall functioning of the world that the mere idea of trying to deflect a megatrend seems implausible. The possibility of deflecting a megatrend is *close to nil*, although there are occasionally some rare possibilities of intervention (Poli 2019).

One of the most serious errors that a futurist can commit is to confuse explorations with megatrends, that is, to say, take a process that, all in all, can still be oriented, as a process about which there is very little that can be done.

Megatrends are often accompanied by secondary trends that move in the opposite direction. For example, the constant global growth of cities is accompanied by an opposite movement of flight from cities back to the countryside. The repopulation of some valleys in the Alps is a good example of this countertrend: after decades of the depopulation of mountain areas, we are now witnessing an opposite flow of people who decide to return to live there. Paying attention to countertrends can be fruitful, because they are often indicators of potential market niches. What really matters is not to confuse one with the other, the dominant megatrends with the secondary countertrends that counteract the former's effects. The following are some examples of megatrends: population growth, aging population, expansion of cities, and increased energy demand. Each of them is able to shape our long-term futures for many decades ahead.

Windows of Opportunity

Table 1 shows the central projection (i.e., neither the most optimistic nor the most pessimistic) of the demographic data published by the United Nations Population Office (UN 2015a, b, 2017).

For their analysis see Poli (2019). Here I only comment on the demographic explosion of Africa.

The expectation of an enormous African demographic explosion stems from the fact that 41% of the African population is in the 0–14 age group and that not yet ongoing in Africa is the demographic shift from five to eight children per

Forecasting, Table 1 UN central projection (in millions)

Region	2017	2030	2050	2100

Oceania	41	48	57	72

woman to one to two children per woman. Two actions can affect this process: sending girls to school and starting to improve the overall quality of life, thereby triggering a certain level of economic development. The first action is quite simple: since teachers and lecturers are underpaid in every part of the world, building and developing a generalized educational system would entail a relatively low cost. African countries should be given inputs, stimuli, and help for the swift development of a new indigenous teaching class. Given extensive and widespread investment in modern educational facilities, this would lead to a rapid increase of literacy in both urban and rural areas. However, the educational path should be long, and it should not stop at primary education. In fact, data show that for Africa, an elementary education would not be enough to free young women from subservience (Zinkina and Korotayev 2014). Education should also be gender-specific, as only female literacy and *upskilling* can guarantee the reduction of an otherwise unsustainable birth rate.

It is difficult to trigger economic development for various reasons: the well-known fragility of African agricultural land, the failure of countless humanitarian interventions, the international exploitation of the continent's natural resources, and the high levels of corruption of many local governments. These are all serious and important problems that cannot be underestimated. Nevertheless, according to data from the World Economic Forum, stable jobs in Africa grew by 3.8% between 2000 and 2015 (with a +1% increase in the workforce, an insufficient, but nevertheless positive, improvement); the strong urbanization in progress contributes to increasing

productivity (cities have productivity three times higher than that of rural areas); and consumption is also growing (with an annual increase of 4.5% between 2000 and 2015). Finally, the ability of Africans to use modern technologies to overcome infrastructural limitations should not be underestimated: East Africa, for example, is already the global leader in mobile payments (Poli 2019).

Back to Forecasting

Understanding the differences between forecasting and foresight can be aided by a short analysis of the axiomatic system developed by Kolmogorov, perhaps the most authoritative source of modern probability theory (Kolmogorov 1956). Kolmogorov's second axiom states that the space of the event to be calculated must be fully specified and closed, otherwise the probability of each single event (or series of events) is meaningless. This is an important limitation: to say that the probability of an event can only be defined if the space of the event is closed is to argue that a probability assessment can be conducted in a significant way only if we know a priori everything that is possible. No break-in of new circumstances, surprise, or unforeseen situations is permissible. This is tantamount to saying that to use probability we must have already tamed the future. As Derbyshire rightly comments, in this situation "the future is merely a shadow of the past and the present" (Derbyshire 2017). For this reason, using probability to address future challenges is "dangerous": because it "forces us to base our view of the future on what has happened

in the past” (Derbyshire 2017). Moreover, Kolmogorov’s third axiom states that the total sum of the probabilities of the events that make up the space of the events amounts to 1. That is, if a new event is added to the space of the events, the probability of the events already included must decrease. After all, there is also room for surprises and new elements, provided that the probability of the events already included is reduced accordingly. This is one of the reasons why surprises, i. e., unexpected events (those on the tail of a probability distribution), end up with minimal probabilities (which ultimately justifies their being set aside).

From Probability to Consequences

What can be done when probabilities cannot be assigned? One solution is to move from probability calculation to consequence assessment: trying to reconstruct the overall picture and focusing on the effects that may occur rather than on the probabilities that cannot be known. Understanding the fragilities of a system and trying to overcome them is much more productive than trying to calculate the probability of an event that could damage that system (Taleb 2012).

Moreover, in order to understand and manage rare events, it is useful to develop multiple perspectives integrating multiple points of view (psychological, sociological, normative, etc.) and different methods. Each of them has its own weaknesses and errors, which partly cancel each other out. When the results of different methods suddenly deviate together in one direction, we have a signal that may announce an incipient pattern change in a previously predictable system (Taleb 2007).

Thirdly, one can try to understand how things work together, their relational nature. This entails grasping situations in their context and explaining how they are related to each other, focusing on patterns rather than facts. There is no doubt that studying the mutual interconnections of various problems is a challenging task that in many cases cannot provide crystal-clear answers. On the other

hand, the difference between information and knowledge lies in the identification of patterns. It is also to be noted that analyzing risks isolated from their contexts involves studying something different from the original phenomenon, because an artificially isolated risk can behave (and as a rule does so) differently from how it would act in its own context.

Anticipatory Risk Management

Anticipatory risk management (ARM) is based on the assumption that the uncertainty of the future cannot be overcome. Uncertainty is exactly what is not addressed by traditional risk management systems, which I call “reactive.” Reactive risk management deals with gains or losses resulting from a probability calculation based on past data. It focuses mainly on the individual organization, proceeds by usually very simplified process schemes, and is based on known rules and risk profiles. Anticipatory risk management, on the other hand, focuses on exploring the uncertainties of unknown risk profiles.

The traditional approach to risk management delegates uncertainty to the accuracy of data and the methods used to measure measurable risks. However, risks must also be managed when data are unreliable or unavailable. For this reason, too, anticipatory risk management places uncertainty at the core of its analysis. It starts with an understanding of the importance of consequences regardless of their statistical significance and focuses on how to influence and manage events and the results that follow. Mitigating uncertainty also means learning to govern ambiguities and positional differences, such as those related to different worldviews (Poli 2016). Structured in this way, risk management is a multidisciplinary enterprise. Moreover, it should be stressed again that the idea of a risk independent of or isolated from its context makes no sense: there is no such thing as a “single risk,” with no relation to other risks.

Another distinctive feature of anticipatory risk management is the time perspective. Like any future-based approach, anticipatory risk

management adopts medium- to long-term time windows, because windows that are too short, like those normally adopted by reactive risk management, make many risks invisible. They disappear from the radar not because they have been addressed, but because the structure of the model adopted does not allow them to emerge. The forward-looking approach and the explicit adoption of medium to long-term time windows help decision-makers and entire organizations to cope better with uncertainty (Furlanetto and Poli 2018).

In normal situations, i.e., with foreseeable changes, anticipatory risk management is not a substitute for reactive risk management. It is in situations of real uncertainty, where the traditional approach is largely inadequate, that a forward-looking approach is indispensable. Unlike reactive risk management, anticipatory risk management recognizes that complex systems are not simply more complicated systems. On the contrary, anticipatory risk management defends the idea that simple systems (including complicated systems) and complex systems are two completely different categories (see the entry ► “Anticipation Systems”).

The perspective of the future aids understanding of why surprises and genuinely unpredictable changes are more significant than continuity. The temptation to look for premonitory signals and justifications ex post calms our anxiety, but it is illusory. The question is why the signals announcing changes are not seen and understood in time. What is surprising about the real estate bubble of 2008 is the number of people who predicted it and announced it in a clear and timely manner. The point is that decisions are taken “forward,” and this is quite different from reconstructing a story ex post.

Anticipation is required because of the uncertainty of the future. What is captured by methods based on the past only covers a few secondary aspects of what is yet to come. In this regard, Derbyshire is crystal clear: the temptation to use what we currently know and to ignore what we do not know, including the ways in which things may change in the future, is a dangerous by-product of the use of probability (Derbyshire 2017), or in Taleb’s terms, it is a dangerous by-product associated with misuse of probability.

What to do, then? A few pointers:

1. Understand that rare events are the new normal, and for this reason they must inevitably become a part of our strategies.
2. Pay attention to the models we use. After all, some events are considered rare just because our models tell us so; what if the problem is also due to the fact that we adopt unsuitable models?
3. Move from probability analysis to understanding the consequences of an event and eliminating the fragilities inherent in organizations.
4. Combine different perspectives and methods. When several indices change in parallel, we may see an incipient pattern change.
5. Study situations in their proper context and how things are related to each other, focusing on patterns instead of facts.
6. Move from the analysis of known, well-defined and confined risks to the exploration of indeterminate or unknown uncertainties (from reactive risk management to anticipatory risk management).

Abstract

Forecasting, Foresight, and Anticipation are considered to be the basic components of Futures Studies. Forecasting deals with data extrapolation; Foresight with the visualization of possible futures; and Anticipation with the translation of their outcomes into action. The overall structure of Futures Studies comprises the differences between megatrend and exploration, risk and uncertainty, and complication and complexity. Finally, the idea of Futures Literacy is introduced.

Uncertainty · Complexity

Introduction

Many futurists see Futures Studies (FS) as overlapping with, or almost defined by, foresight processes and methods. Indeed, the distinction

among different components of FS (which I will call “forecasting,” “foresight,” and “anticipation”) emerged from the evolution of FS itself. Early contributions to FS did not distinguish among them (de Jouvenel 1967; Ringland 1998; Schwartz 1991). As Cuhls notes, “initially (they) were used equivalently” (Cuhls 2003, p. 95). Subsequently, some distinctions were drawn, although they were usually characterized by areas of overlap (Cuhls 2003). Sometimes the overlap was between forecasting and foresight (Armstrong 2001), sometimes between foresight and anticipation (usually termed “planning,” see below), as with the expression “scenario planning” (Ringland 1998), sometimes among all three (Porter 1996). There are also a substantial number of futurists who have openly denied that forecasting methods pertain to FS. To make matters even worse, foresight has been variously interpreted as cognitive ability (Gary 2009; Hayward 2003; van der Laan and Erwee 2012), as organizational capability (Hines et al. 2017; Rohrbeck 2010; Rohrbeck and Kum 2018), as a process (Voros 2003), and as many other things as well.

In recent years, a new position has begun to surface. It advocates a sharper structuration of FS, and its main claims can be summed up in the following three theses:

1. The difference between forecasting and foresight is sharp, meaning that there is no smooth transition between them (Poli 2019; Tuomi 2019).
2. The reference to planning as the third component of FS is overly restrictive. Planning is only one way to use the future. The new, growing field of Futures Literacy provides the framework in which to distinguish different ways to using the future (Miller 2007, 2011, 2018). We therefore need a covering term ampler than “planning.” I will use “anticipation” as the name of the third component of FS (Poli 2017). It goes without saying that the connection between FS and FL should be clarified.
3. The distinction among “forecasting,” “foresight,” and “anticipation” is too indistinct and needs to be expanded in different directions to

develop positive connections between FS and the sciences (Poli 2019).

Forecasting, Foresight, and Anticipation

The new position sees FS as organized into the three sectors of “forecasting,” “foresight,” and “anticipation.” Put briefly, forecasting deals with data extrapolation, foresight with the visualization of possible futures, and anticipation with their translation into action.

Accepting that forecasting is actually a minimal component of FS is different from claiming that forecasting does not pertain at all to FS.

The purpose of the distinction between forecasting and foresight, on the one hand, and anticipation, on the other, is to avoid including widely different activities under the same rubric. There is a clear difference between representational activities, such as those aimed at extrapolating data, or visualizing different possible futures, and actions aimed at translating the former activities into strategy and action. For this reason, I prefer to clearly distinguish between forecast (extrapolation of data) and foresight (visualization of possible futures), on the one hand, and anticipation (translation of what has been seen into decisions and actions) on the other.

Thirdly, by adopting only one overarching category (foresight) and failing to distinguish among forecast, foresight, and anticipation, mainstream FS are unable to provide a framework that is able (i) to include further distinctions, such as those among megatrend and exploration, risk and uncertainty, and complexity and complexity, and (ii) to establish a dialogue with science, especially the human and social sciences (Poli 2017, 2019).

Finally, I shall also discuss forecasting and foresight as model-based activities. The concept of model that I adopt is very broad (Rosen 2012). Here the term “model” does not refer only or mainly to the formal models used by scientists; rather, it refers to any process, framework, structure, or activity that seeks to capture the development of a situation, a problem, or a phenomenon

under observation. In my conception, a model is any activity that looks forward to what might happen. According to this meaning, even fears and hopes are models (Poli 2016).

For further information on forecasting, see the entry ► “Forecasting”; for anticipation see the entry ► “Anticipation”. In what follows, I focus only on foresight.

When we deal with information that is not exclusively quantitative or with unreliable quantitative information, we need models that are different from predictive ones. In fact, the vast majority of models are not predictive.

Understanding the distinction between future (singular) and futures (plural) is often the first step in understanding how forecasts and foresights differ. We do not read *the* future: we do not have crystal balls; we do not read tarot cards; even less do we inspect the entrails of chickens. Anyone who claims to know how things are going to develop is a charlatan. Nevertheless, there is something we can do to try to understand how events might develop. We can discover *some* possible futures that will help us keep in mind the different ways in which reality might reveal itself. Central to this circumstance is therefore the passage from the singular of the future – almost as if it were there, in front of us and our only possibility were to go from where we are now to that particular place, along a path already traced – to the plural of futures. Things can go different ways, and if we see them, we can try to prepare and not be overwhelmed by new situations.

When we move from an implicit idea of the future to an explicit idea of it, a number of operational frameworks open up. First, the value of foresight emerges: seeing the ways in which situations can evolve enables us to try to prepare ourselves – we may not succeed, but at least we can try. The explanation of the possible futures linked to foresight also has clear ethical relevance: if one sees what might happen, one must take responsibility for what one will do or not do. It should also be noted that, as natural as it may be to refer to the future as the cradle of oncoming problems, this is still only a partial view. Problems are never separated from opportunities. Where there are

problems, there are also opportunities to be exploited. In both cases, the logic is the same: if we see the process that is under way, we can try to intervene; if we do not see it, we may be overwhelmed by adversity, or we may not grasp its potential.

This is all correct, but it conceals a problem. Forecasts are also often made in the plural (central projection, higher, lower) and may have various levels of confidence: for example, climate change models include ranges of extrapolations to the future. The difference lies in the way in which the future is made explicit: in the case of forecast, the future is constructed as a repetition of patterns from the past, while in the case of foresight, the future also contains authentic innovations and discontinuities (Derbyshire and Wright 2017; Tuomi 2019). A model of the future that does not include surprising changes is not a true model of the future.

Expanding the Framework

The difference among forecasting, foresight, and anticipation constitutes the first layer of FS. One needs further thematic layers to represent the richness of FS better. The overall structure is schematized in Table 1 (Poli 2019).

For each layer, the last factor is permanently linked to anticipation, i.e., the component responsible for translating the results of model representations into action. The first two factors, on the other hand, refer to different classes of models: megatrends, risk models, and complicated systems belong to the category of forecast models; explorations, uncertainty models, and complex systems belong to that of foresight models. The basic architecture therefore remains constant across the different layers.

Megatrends and Explorations will be further discussed in the entry ► “Forecasting”.

Risk and Uncertainty

Surprises are basically of two different types. The first type is only a surprise because we use schemes for analysis that are too narrow; that is, they depend on how we frame the problem. By modifying the frame, one often discovers that in the end the surprise could have been foreseen, and, therefore, was not a real surprise. The expression “black swan” is used today to refer to an event that is virtually impossible in relation to a certain (temporal and spatial) context but becomes possible if transposed into a broader one (Taleb 2007). Although black swans in themselves are rare occurrences, today we see them in many different areas: climate, geopolitics, economics, technology, fashion, etc. All together they are numerous. If we then consider their reciprocal interactions, which result in cascading effects, we are almost forced to consider black swans as “normal” events.

Surprises can also be of a different type. Some surprises are independent of our analytical frameworks and concern situations that can in no way be anticipated: they are real surprises. They refer to rare events, with high impact, outside any radar. In this case, futurists speak of *wild cards*. I will use the term *risks* for the unforeseen events linked to our analyses (the first type of surprise described above) and *uncertainties* for real surprises (the second type).

Risk and uncertainty concern a further aspect of the difference between forecasting and foresight, which relates to process management.

My thesis is that there is a clear distinction between risk and uncertainty: the two terms refer to different classes of events between which there is normally no border that can be crossed. An uncertain event is not simply an event with a lower probability of occurrence; rather, it is an event for which there is no significant probability calculation. Some of the most striking errors

Foresight, Table 1 The layers composing Futures Studies

Layer 4	Complicated	Complex	Anticipatory
Layer 3	Risk	Uncertainty	Anticipation
Layer 2	Megatrend	Exploration	Anticipation
Layer 1	Forecasting	Foresight	Anticipation

committed during the recent economic crises have been due precisely to the inability to distinguish between risk and uncertainty. The real uncertainty of the future cannot be mistaken for risk, and no “siren call of probability,” as Derbyshire says, can alter this fact (Derbyshire 2017).

The vast majority of future events are uncertain, in the sense explained. Otherwise, only a small minority of future events are susceptible to probability assessments, just as only a small proportion of events are predictable.

The difference between risk (calculable) and uncertainty (incalculable) is not a new notion. Some classic sources are Knight, Keynes, and Shackle (Keynes 1921; Knight 1921; Shackle 1955). Keynes could not be clearer: with regard to uncertainty, he writes “there is no scientific basis on which to form any calculable probability whatever.” What can an analyst do when she/he cannot assign probabilities? One solution is to move from probability calculation to consequence assessment: the analyst seeks to reconstruct the overall picture and focuses on the effects that may occur rather than on the probabilities that cannot be known. Understanding the fragilities of a system and trying to overcome them is much more productive than trying to calculate the probability of an event that could damage that system.

Complicated and Complex

Complicated, complex, and anticipatory represent the third iteration of the difference among forecasting, foresight, and anticipation. As listed in Table 1, the two intermediate stages were megatrends, explorations, and anticipation and risk, uncertainty, and, again, anticipation. Each time the analysis goes deeper, the first term of the triads gathers the aspects most explicitly related to the scientific mainstream.

Each iteration comprises a crucial step. The one from forecasting to foresight (and then, analogously, from megatrend to exploration, from risk to uncertainty, and from complicated to complex) can be more or less adequate for the effort necessary. It is like throwing a ball up a hill: if the throw is not strong enough, the ball will come back and

not make it over the slope. Many attempts to go “beyond” forecasting, megatrends, risks, and complications fail precisely because the throw is not decisive enough (Poli 2019).

Moving from forecasting to foresight requires more than moving from one future to multiple ones. It is also necessary to verify that the generative mechanism of new futures is not limited to including repetitions of the past. Similarly, the transition from megatrends to explorations cannot be reduced to the difference between one and many. Instead, it requires the presence of genuinely open variables, which can yield very diverse outcomes. The shift from risks to uncertainties does not stop at the greater or lesser extent of the analytical frameworks; it implies the absence of a probability distribution. Each of these cases exemplifies the unyielding openness of the future (Tuomi 2019).

Complexity studies are perhaps the main development in contemporary science. They show that the traditional positivist perspective is an illusion to be definitively abandoned. In the case of complex systems, the best that we can do is “learn to dance with them” (Meadows 1999). Their dynamics must be followed, accompanied, and gently led in the direction that seems most appropriate, knowing that each intervention can generate – and usually does generate – unforeseen effects. For this reason, it is important to “feel” the system, to test the steps to be taken in constant interaction with it, moving gently and being ready to take a different action if necessary. In this perspective, the theory of anticipatory systems is the most sophisticated theoretical framework currently available to us. But, as often happens with new ideas, complexity has also been defined in many different ways, so much so that each research group seems to have developed its own distinctive meaning.

Futures Literacy (FL)

FL refers to the ability to use the future actively in the present (Miller 2007, 2011, 2018; Poli 2017).

First of all, however, we must bear in mind what is meant by “literacy.” At a first level, we

all know what it means: literacy means the basic skills that we all acquired during the years of compulsory schooling, namely, the grammar of our language, knowing how to read and write correctly, and being able to perform some elementary arithmetic operations. This definition is unquestionably correct but also exceedingly superficial. Literacy is in fact much more.

At a deeper level, the development of reading, writing, and counting skills, besides obviously having required the acquisition of certain technical abilities (such as the rules of grammar), is a fundamental source of freedom for millions of people. By knowing how to read and write, everyone is able to express an idea; to develop a point of view; to collect information; and to express and defend their dignity. To demonstrate this, a simple counterfactual suffices: today, a person who cannot read and write is socially marginalized.

There is no doubt that the skills that have characterized traditional forms of literacy remain essential today. The question, however, is whether they are sufficient to deal with the challenges of the twenty-first century. The complexity of this particular historical period seems to require the development of further skills which enable people to orient themselves within increasingly uncertain contexts characterized by incessant changes and marked by surprising technologies and novelties. The information of the past and the experience developed hitherto are no longer able to show the way. People need to broaden the information base on which they make decisions. But where can they go to find new directions? If the past is no longer enough, what remains is looking to the future. The future is precisely the source of the wider information base that people need.

As with traditional forms, new forms of literacy are also tools of freedom that enable people to orient themselves, develop opinions, take positions, and defend their dignity. Just as the former proved to be a socially important force when they became a mass phenomenon, the latter will also have a powerful impact on society if they become widespread. Minorities able to read and write have always existed, as have consultants for governments and large companies; the revolution occurred when the literacy process began to affect

the masses, and the same will happen for future skills.

Like former kinds of literacy, FL implies the acquisition of certain skills, i.e., those necessary to classify and use the future in an appropriate way. The main skills are the ability to distinguish among different types of futures and to identify different ways to use the future in the present. As regards the former, a standard distinction within futures studies is that among possible, plausible, probable, and preferable futures (Amara 1981):

- The scope of possible futures is the broadest and includes all the futures that we can imagine, even those that exceed the knowledge and the abilities that we have developed so far (i.e., warp speed or teleportation from *Star Trek*).
- Plausible futures are a subset of possible futures and include those that could actually occur according to the knowledge available to us.
- Probable futures constitute a further restriction; they refer to futures linked to trends that we are able to observe, including possible minor deviations.
- Finally, preferable futures are very different from those considered so far: while possible, plausible, and probable futures pertain to a descriptive level of analysis, preferable futures are clearly normative. It's about the futures we'd like to live in.

For example, consider the space program launched by US President John F. Kennedy in the early 1960s. When the project was presented, it was mere speculation, nothing but a possible future, because the knowledge required to send a person to the Moon was not yet available. During the 1960s, the necessary technology was developed and the future that once had only been imagined became first plausible, then probable, and finally, on 20 July 1969, real. The progression of this simple case shows that the classification of futures also depends on the time from which they are evaluated: the judgment inevitably changes as things evolve.

With regard to the different ways of using the future, however, I will expand Miller's distinction among optimization, preparation, and novelty:

- Optimization sees the future as separate from the present and selects a specific future of reference. Its motto is "I'm moving into the future." Analytically, the focus can be on the next phase (incremental innovation) or on the final result (planning).
- Preparation also perceives the future as separate from the present moment. Unlike optimization, however, preparation naturally takes into account a variety of different futures. Its motto is "the future is coming at me," from a direction that may or may not be detectable. As a result, attention can be directed in specific, selected, and visible directions or in vague, unclear, and indeterminate ones.
- Lastly, novelty sees the future directly in the present, which distinguishes it from optimization and preparation. From an analytical point of view, the attention can be more focused on ideas (concepts, values) or practices (behaviors, learning). The motto is "the future is already emerging in the folds of the present": by better understanding the present situation, digging into its depths, we can glimpse the future in formation.

While futures literacy is still in its early stages of development, it is clear that it can greatly increase the social ability to "see" the future – in the same way that reading and writing have increased people's capacity for citizenship.

Summing up, FL is part and parcel of FS. FL is the basic, non-technical version of FS, the competences that everybody should acquire. Under no circumstances is the intention to "know the future"; rather, it is a question of enabling people, organizations, and communities to make explicit choices among different possible futures (Miller 2018). The challenges to be faced in the coming decades will require citizens to be increasingly aware and able to make important decisions; in this sense, futures literacy

promises to be the basis necessary to arrive, perhaps, at shared choices.

Conclusion

This entry has sketched the different layers that make up FS, both horizontally and vertically. The initial division among forecasting, foresight, and anticipation (horizontal plans) was subsequently ramified by introducing analysis by megatrends and explorations, by risks and uncertainties, and by complicated and complex systems (vertical plans). This shows that futures studies constitute a sophisticated theoretical field that has the capacity to develop relationships with many scientific disciplines.

Frankenstein

Flora Lisica

Northeastern University London, London, UK

Abstract

Frankenstein; or, The Modern Prometheus is a novel by Mary Wollstonecraft Shelley (née Godwin; 1797–1851), published in 1818 and revised in 1831. It tells the story of Victor Frankenstein, who constructs and animates a sentient and sapient creature in a scientific experiment, only for the experiment to end in disaster as, rejected by Frankenstein, the creature revenges himself upon his creator.

Frankenstein is considered one of the earliest examples of science fiction, and, inspiring countless theatrical and cinematic adaptations, the scientist and his creature have evolved into cultural icons. As such they are important cultural metaphors and have been helping us think about questions partaking to our conceptions of humanity, and opening up new possibilities as to how we view our past, present, and future, for over two centuries.

This entry begins by explaining the background to *Frankenstein*'s composition, publication, and its cultural impact since, before outlining the novel's plot. It then focuses on some of the novel's central thematic preoccupations to do with the possibilities of human sympathy and science. These questions have been central in literary critical interpretations of Shelley's novel, as well as being integral to the importance of the story of *Frankenstein* as a cultural myth.

Keywords

Frankenstein · Mary Shelley · Possible · Science fiction · Literature

Introduction

The figures of the scientist and the sentient yet frighteningly destructive creature which he has brought to life are immensely familiar, even verging on the cliché. Since they were brought into existence in Mary Shelley's novel *Frankenstein; or, The Modern Prometheus*, published in 1818, they have been adapted for the theater, the cinema, and television, as well as directly or indirectly inspiring and appearing in other literary works, graphic novels, films, and television series. Indeed, some have argued that Shelley's narrative has had a stronger presence in popular media than any other over the past two hundred years (Cutchins & Perry, 2018, p. 1).

In popular culture, the characters of Frankenstein and his creature have sometimes appeared as the cartoonish mad scientist and his monster, but Shelley's novel ultimately continues to fascinate and frighten its readers by portraying both Frankenstein and his creature with great nuance and complexity. One of the earliest examples of science fiction (Mellor, 1988, p. 89), *Frankenstein* helped develop the genre's interest in the relationship between the possible and the impossible, specifically through its complication of our definition of the human, and our agency over this definition both through social organization and scientific advancement—questions which remain as pressing in our own time as they were at the time of Shelley's writing.

This entry explains the background to Shelley's composition and publication of *Frankenstein*, briefly indicates its reception, and provides a summary of the novel's plot. It then outlines some of the more prominent ways that *Frankenstein* has been approached by literary critics in recent decades, focusing, particularly, on readings of two central thematic preoccupations of the novel: Shelley's exploration of the possibilities of what might be understood as human, and the opportunities and dangers represented by scientific innovation. In these ways, *Frankenstein* continues to be important for our contemplation of what is, or could be, possible, both socially and scientifically.

Composition, Publication, and Reception

Shelley was the daughter of two important writers of fiction and political philosophy. Mary Wollstonecraft (1759–97) is celebrated for *A Vindication of the Rights of Woman* (1792); arguing for the improvement of women's access to education, it is considered an early work of feminism. William Godwin (1756–1836) is best remembered for *An Enquiry Concerning Political Justice* (1793), a critique of social institutions, where he offered a protoanarchist vision of human progress as dictated by reason. Shelley was strongly influenced by their work, as well as by the work of her partner (from 1814; husband from 1816) Percy Bysshe Shelley (1792–1822), a poet known for his radical political and social views (Smith, 2016a, pp. 2–3).

Shelley began working on *Frankenstein* when staying in Geneva in the summer of 1816, aged 18. She later traced her conception of the novel to an evening which she spent in the company of P. B. Shelley, the poet George Gordon Lord Byron (1788–1824), and writer and physician John William Polidori (1795–1821), when they decided to each write a “ghost story” to amuse one another (Shelley, 1992, p. 7). Shelley completed the novel in the spring of 1817, and, after being edited by P. B. Shelley, it was published anonymously on 1 January 1818, with a dedication to Godwin and a preface by P. B. Shelley (Seymour, 2000, pp. 189–195).

Frankenstein was not an immediate success, but it was translated into French in 1821, and adapted for the London stage for the first time in 1823, prompting Shelley to republish the novel with her name on the title page the same year. She produced a new edition of *Frankenstein* in 1831, making alterations to some of the language, characterization, and, occasionally, elements of the plot, as well as including a new preface (Robinson, 2016 19–21). The 1831 edition has been the most commonly republished, though some critics have argued for the superiority of the 1818 edition (Mellor, 1990). This entry chiefly refers to the 1831 edition, making occasional reference to the edition of 1818.

The 1823 stage adaptation of *Frankenstein* was a triumph and prompted a series of others; at least 96 adaptations have been documented to have been staged before 1990 (Forry, 1990, pp. 121–126). There have also been 41 silent films with *Frankenstein*-related themes, and at least 200 film titles which include the word “Frankenstein” are catalogued by the IMDB (Friedman & Kavey, 2016, pp. 93, 101). These adaptations stand at varying degrees of proximity to Shelley’s novel, many taking substantial liberties with both the story’s plot and Shelley’s characterization, but they have also been essential in establishing and maintaining *Frankenstein*’s cultural significance and have continued exploring the ideas introduced by Shelley’s novel.

Plot Summary

Shelley’s novel opens with Captain Robert Walton, an explorer sailing toward the Arctic, coming upon Victor Frankenstein by chance on his journey. Ill and weakened by the cold, Frankenstein is brought onto Walton’s ship and narrates the events which had brought him to the Arctic.

Frankenstein had grown up in Geneva together with his adopted sister Elizabeth Lavenza (she is portrayed as a cousin in the 1931 edition), and in the company of his friend Henry Clerval. He had gone on to pursue the study of the natural sciences at university in Ingolstadt, where he became obsessed with the desire to uncover the source of life in order to utilize it for human gain. He eventually constructs a humanoid creature from the parts of human and animal corpses and succeeds in animating it – only, he comes to see his experiment as a mistake the moment the creature displays signs of life. Eight feet tall and disturbingly unattractive, the creature is grotesque, terrifying, and Frankenstein believes that its physical properties are likely to be an indication of his malice. Racked with guilt, Frankenstein flees his workshop, leaving the creature to fend for himself.

Time passes, and Frankenstein hears of his younger brother William having been murdered in Geneva. Frankenstein believes that his creature must have been involved, but the family servant

Justine is accused of the murder instead, having been looking after William shortly before his death, and, in the absence of an alternative suspect, she is executed.

The remorseful Frankenstein is then confronted by his creature, who explains how, after his escape from Frankenstein’s workshop, he found himself treated with violence and contempt by people who are all, like his creator, horrified by his appearance. The creature retreated from civilization and found shelter in an abandoned hovel attached to a cottage. The family inhabiting it was unaware of the creature’s presence, but as he observed their daily lives, he grew extremely fond of them, performing small tasks of kindness for them without their knowledge. He learnt to speak from overhearing the family members converse with each other and taught himself to read from books he discovered in the forest. But while he began befriending the blind father of the family, the rest of them reacted to the creature’s presence with great hostility, and he fled from the cottage.

Enraged and miserable, the creature traveled to Frankenstein’s family estate, where he murdered William and framed Justine. Seeing no prospects of being integrated into society, the creature is acutely lonely, and furious with Frankenstein. The creature demands that Frankenstein create a female companion for him, promising that the two of them would make sure to stay away from Frankenstein and the rest of humankind, and threatens to destroy Frankenstein’s life if he does not comply.

Frankenstein reluctantly agrees and begins working on the female creature with great unease. He is especially troubled by the possibility of the two creatures reproducing, and, having witnessed the effects of his creature’s anger, he worries that he may be creating a race which will terrorize and obliterate humankind. Frankenstein eventually destroys the female body he had assembled before bestowing it with life, and the creature retaliates by killing not Frankenstein but his loved ones, first murdering Clerval, and strangling Elizabeth on her and Frankenstein’s wedding night. Frankenstein then begins pursuing the creature, in hope of destroying him once and for all, which eventually brings him to the North Pole.

Frankenstein dies shortly after recounting his story to Walton, and Walton's expedition is brought to a halt as his ship encounters difficulties, and his crew demands that they return south. Upon Frankenstein's death, the creature comes to Walton's ship to mourn his creator and, feeling entirely alone in the universe and remorseful of his actions, vows to commit suicide (Shelley, 1992, 1998).

Critical Interpretations

While Shelley's work was a strong presence in popular culture of the nineteenth and twentieth centuries, it did not receive a great deal of attention from literary critics before the 1970s, when it rose to prominence as feminist revisions of literary history and the literary canon resulted in the reassessment of works by female writers. Since then, *Frankenstein* has been a seminal text in the broadening of the literary canon to include more works written by women, and for the testing of the possibilities offered by feminist approaches to literature more broadly. Indeed, Long Hoeveler argues that *Frankenstein* has "figured more importantly in the development of feminist literary theory than perhaps any other novel" (Long Hoeveler, 2003, p. 45).

A number of feminist readings have taken Shelley's biography as a starting point to think about *Frankenstein* in light of Shelley's gender and the possibilities available to female writers. Some readings of *Frankenstein* have focused on the relationship between Frankenstein's creation of the creature and maternity, particularly in light of Shelley's pregnancies and childbirth in the period of writing (Moers, 1976, pp. 92–99; Mulvey-Roberts, 2000). Others have explored Shelley's relationship to Godwin, Wollstonecraft, P. B. Shelley, and their literary outputs (Knoepfmacher, 1974), or the novel as a reflection on female authorship in the context of the male-dominated literary history and culture of Shelley's time (Gilbert & Gubar, 1979, pp. 213–247; Johnson, 1982).

These readings have remained influential for critics considering *Frankenstein* in more recent

decades, who have often focused on situating the novel in its historical contexts. The questions critics have been asking about the novel's engagement with the possibilities and limitations of humanity, and how that definition of humanity might be expanded or limited by the promises of scientific advancement, are ones which remain relevant for *Frankenstein's* readers at large, as well.

Frankenstein and the Idea of the Human

Central to *Frankenstein* is the question of the possibilities and limits of what could be considered human. When the reader first encounters the creature, recounting his history to Frankenstein, he is eloquent, thoughtful, and reflective; Frankenstein himself observes that he is "rational" and "a creature of fine sensations" (Shelley, 1992, pp. 209, 141). Nonetheless, inspiring fear and disgust with his appearance, he is shunned from society, and Frankenstein and the rest of mankind find it impossible to recognize him as a fellow human.

A number of critics have read Shelley's inquiry into the possibilities of what might be deemed human as a metaphor for the different social groups facing similar kinds of rejection as the creature. In that vein, critics have read Shelley's portrayal of the creature as a comment on race relations in Europe at the time of her writing. The creature himself expresses sympathy with non-Europeans on two occasions, lamenting the fate of the original inhabitants of America, and the treatment of a Muslim immigrant in France (Shelley, 1992, pp. 116, 119). Mellor argues that the creature's appearance evokes early-nineteenth-century conceptions of what was believed to be the Mongolian race (2001), for instance. Others have regarded Shelley's description of the creature's appearance as drawing upon European perceptions of Africans and West Indians in the period, with the novel thus emerging as a critique of European imperialism. While the Slave Trade Act of 1807 prohibited the slave trade in the British Empire, it did not end the practice, and Shelley was clearly invested in the issue, reading works on the slave trade, and partaking in a sugar boycott because it came from

West Indian plantations which employed slave labor (Seymour, 2000, pp. 138–139). Thus, Malchow sees the novel as engaging with the “fears and hopes” of the abolitionist movement (Malchow, 1996, p. 9), and Mulvey-Roberts reads the creature’s journey as evoking both slave narratives and the history of slave uprisings (Mulvey-Roberts, 2016, pp. 52–91), while Young has perceived the reception of Shelley’s novel in the United States, and the emergence of Frankenstein and his creature as cultural symbols over the last two centuries as specifically racially charged (Young, 2008).

Frankenstein has also been read as invested in questions of class and economic difference, especially as a reading of the events of the French Revolution (1789–1799). Although Shelley does not give an exact date for her novel’s setting, the events have been commonly assumed to be taking place in the decade preceding the Revolution (Goodall & Knellwolf, 2008, p. 4). Frankenstein attends the University of Ingolstadt, which was in the period associated with the Illuminati, a group united by its members’ interest in radical science and the supernatural, as well as by their support of the Jacobin cause. Indeed, an affinity was perceived between scientific exploration and political radicalism in the period more broadly. In 1791, the laboratory of scientist Joseph Priestly (1733–1804) was burnt down by an anti-Jacobin mob in protest of his revolutionary sympathies (Smith, 2016b, pp. 74–75), while some writers applied metaphors of animation to the spirit of the French Revolution in order to argue both for its power to enliven the social body, and for its destructive potential (Ruston, 2005, p. 2). Some critics thus read Shelley’s characterization of the relationship between Frankenstein and his creature in light of the metaphorical use of monstrosity in discussions surrounding the French Revolution. Critics of the French Revolution, such as Augustin Barruel (1741–1820) and Edmund Burke (1729–1797), analogized Jacobins with monstrous children revolting against their benevolent parent, embodied by the king. But the metaphor was also adopted and turned on its head by pro-Revolutionary writers including Godwin, Wollstonecraft, and Thomas Paine (1737–1809).

They argued that the monstrosity of a child can be traced back to the monstrosity of their parents, and so the monstrosity of the Terror was a retaliation to the ill-treatment of the people under the *Ancien Régime*, with its unjust systems of wealth, rank, and privilege (Sterrenburg, 1979, pp. 154–157; Baldick, 1987, pp. 16–25).

The creature explains that he was initially “benevolent,” motivated by “the love of virtue, the feelings of happiness and affection” (Shelley, 1992, pp. 87, 97, 213). He ascribes his destructiveness to the unanimous rejection by all those whose sympathy and affection he had sought: “I am malicious because I am miserable; am I not shunned and hated by all mankind?” (Shelley, 1992, p. 140) he contends. Before commencing his tale, the creature places his hands over Frankenstein’s eyes, so that Frankenstein might hear the creature’s story uninfluenced by his disgust at the latter’s appearance, but Frankenstein refuses, pushing away the creature’s hands (Shelley, 1992, p. 98). After hearing the creature’s story, Frankenstein finds himself conflicted: “I compassionated him and sometimes felt a wish to console him, but when I looked upon him, when I saw the filthy mass that moved and talked, my heart sickened and my feelings were altered to those of horror and hatred,” and Frankenstein concludes that he “could not sympathise with [the creature]” after all (p. 142). Theatrical and cinematic adaptations of *Frankenstein* have tended to exploit the visual nature of their respective mediums and have, ever since the 1823 production, typically portrayed the creature as mute, while going to great lengths to affect viewers with his grotesque appearance (Friedman & Kavey, 2016, pp. 81, 104). The novel, contrastingly, as some critics have shown, gives the creature the opportunity to be heard by its readers who, like the blind father of the cottagers, are not affronted by the creature’s appearance, and tend to be sympathetic. Thus, Marshall argues that *Frankenstein* enquires into the logic of sympathy by focusing on the difference between sight and language (Marshall, D., 1988, pp. 178–228), while McLarren Caldwell reads the novel as a critique of the idea of sympathy as based on resemblance and identification, instead inviting the reader to

sympathy which accounts for and accommodates difference (McLarren Caldwell, 2004, pp. 25–45). In these ways, *Frankenstein* continues to speak to our contemporary interest in questions partaking to empathy and perspective-taking and helps broaden the possibilities of who and what we might think of as deserving of sympathy.

***Frankenstein* and the Possibilities and Ethics of Science**

Frankenstein also displays an overt interest in the possibilities and perils involved in scientific research and technological invention. It has often been read as a warning about the potential dangers of science, where the promise of discovery can lead researchers to disregard ethical realities (Mellor, 1988, p. 114); Friedman and Kavey observe that *Frankenstein* is “the most influential cautionary tale ever written” (Friedman & Kavey, 2016, p. 15). Thus, *Frankenstein* and his creature have been used as shorthand for ethically questionable scientific experimentation and technological advancement and are frequently invoked in discussions surrounding industrialization, mechanization, cloning, robots, genetically modified agriculture, and genetic engineering more broadly, among others (Clayton, pp. 84–86; Goodall and Knellwolf, p. 1; Friedman & Kavey, 2016, pp. 64–65). *Frankenstein*’s parting words to Walton give support to such readings: “seek happiness in tranquillity, and avoid ambition, even if it be only the apparently innocent one of distinguishing yourself in science and discoveries” (Shelley, 1992, p. 210). This interpretation has also been given prominence in many of the novel’s adaptations, beginning with the play of 1823, which, entitled *Presumption; or, the Fate of Frankenstein*, presented the story as a tale of the dangers of hubristic pride and ambition which uncovers the disjunction between the scientifically possible and ethically permissible (Forry, 1990, pp. 135–160).

In this vein, Mellor sees Shelley as condemning research which goes beyond describing the natural world and attempts to change it (Mellor, 1988, p. 89), and a number of critics have traced the ways in which the scientific attitudes represented in *Frankenstein* can be read as a

critique of exploitative and ethically questionable scientific practices of Shelley’s time. Marshall has observed how the process of *Frankenstein*’s education about human anatomy in “vaults and charnel houses,” and his assembling of the creature’s body from parts found in “the dissecting room and the slaughter-house” (Shelley, 1992, pp. 50, 53), reflects the ethically contentious use of human corpses by medical professionals in the period, for example. While only bodies of executed criminals were permitted to be used for medical dissection according to the Murder Act of 1752, the high demand for bodies to be used for medical purposes resulted in grave-robbing and an illegal trade in corpses, until the passing of the Anatomy Act in 1832, which gave medical professionals the right to dissect donated bodies (Marshall, T., 1995, pp. 20–23).

Similarly, early-nineteenth-century experiments with electricity were met with distrust by some. Shelley implies that *Frankenstein* employs electricity in order to animate his creature; he becomes fascinated by the phenomenon as he sees an oak tree hit by lightning in a storm (Shelley, 1992, p. 40). In the 1818 edition, this episode is followed by *Frankenstein*’s father constructing an “electrical machine” to conduct experiments, and flying a kite in the storm in a manner which invokes the famous experiment of the same kind conducted by Benjamin Franklin (1705–1790) (Shelley, 1998, p. 23). Researchers including Franklin had been exploring ways of channeling the electric current, and its potential for human use, over the course of the eighteenth century, but the phenomena and its possible applications were by the early 1800s not yet fully understood. In her 1831 introduction to *Frankenstein*, Shelley recalled being inspired by conversations about early experiments in electricity, some of which gained controversy at the turn of the century. The practice of connecting animal corpses to the electric current, named “galvanism” after its originator Luigi Galvani (1737–1798), in order to observe the corpses’ movement due to muscle contractions, became notorious after one of Galvani’s followers made a public demonstration of the experiment by employing the body of a recently executed murderer (Goodall and Knellwolf, p. 7).

Although modern-day research is much more invested in the autonomy of each individual over their own body, the questions about the relationship between the technically possible and ethically desirable raised by *Frankenstein* remain relevant. Helman takes the novel's story as an important metaphor for thinking about the human body in medicine and society more broadly today (Helman, 1992), for example. The novel has also inspired readings which focus on the human interference into the natural environment (Morton, 2016), as well as questions partaking to artificial intelligence and the posthuman (Clayton, 2003; Mousley, 2016).

But a number of critics have also contemplated the significance of the novel's subtitle, "*The Modern Prometheus*," which suggests a more ambivalent attitude toward science. Shelley here draws a parallel between Frankenstein and Prometheus, who according to Ovid created the first human by mixing together earth, water, and air. In doing so, however, Prometheus disrupts the fragile equilibrium of the newly shaped cosmos, where order had only recently been imposed upon the primordial chaos by the elements' separation; the humanity he creates is, like Frankenstein's creature, an embodiment and source of chaos and disorder (Liveley, 2018, pp. 26–27). According to both Ovid and Aeschylus, Prometheus disobeys the gods even further by presenting humanity with fire, and by implication with civilization (Priestman, 2018, pp. 44–45); the link between the gift of fire and electricity was made by Shelley's contemporaries, with Franklin being called "the Prometheus of modern times" due to his experiments (Priestman, 2018, pp. 44–45). Prometheus, like Frankenstein, is severely punished for his disobedience – he is chained to a rock in the Caucasus, with his liver being eaten by an eagle, only to grow back again overnight so that his punishment can continue for eternity. But significantly, Prometheus was regarded as a heroic figure by many of Shelley's contemporaries, including Godwin, P. B. Shelley, and Byron, emerging as a symbol of creativity and noble revolt against an arbitrary authority and constraint (Barnett, 2018, p. 85).

Similarly, Frankenstein's experiment suggests some of the genuine sense of excitement prompted by contemporary scientific discoveries. "Perhaps a corpse would be re-animated; galvanism had given token of such things" Shelley writes in her introduction (Shelley, 1992, p. 8), and Goodall and Knellwolf emphasize that the misgivings about science in the novel are qualified by the context of scientific innovation as an overwhelmingly powerful force of good and social improvement at the time of Shelley's writing (Goodall & Knellwolf, 2008, p. 2). And indeed, Frankenstein's experiment has encouraged scientific discovery as well as caution: Dr. Jean Rosenbaum, who invented a pacemaker in the 1950s, took his inspiration from the use of electricity for the creature's animation in the 1931 *Frankenstein* film (Friedman & Kavey, 2016, pp. 67–68). Thus, Shelley's *Frankenstein* testifies to the importance of fiction, and perhaps science fiction especially, as not only warning readers against the dangers of an unrestrained imagination, but also opening up trajectories of what might be considered possible, and the subsequent possibility of the imagined becoming actualized as a force for good.

Summary

Frankenstein is a novel with an immense cultural presence, generated both by Shelley's text itself and its countless cinematic and theatrical interpretations. The story of Frankenstein's creation and animation of a creature who turns against him and causes his destruction has become a cultural myth, our interest in it perpetuated by our continual interest in the limits of the possible. Shelley's novel has generated a number of critical interpretations, which speak to the richly multifaceted nature of Shelley's novel. *Frankenstein* has for the last two centuries carried out the important work of aiding us in our engagement with uncertainties partaking to our sense of our own humanity in light of our understanding of our past and present, and our aspirations and fears partaking to our vision of the future.

Future Problem Solving

Connie Phelps

Emporia State University, Emporia, KS, USA

Abstract

Future Problem Solving (FPS) engages students in futuristic thinking through annual academic competitions at local, state, regional, and international levels. Hosted through Future Problem Solving Program International (FPSPI), its mission *develops the ability of young people globally to design and achieve positive futures through problem solving using critical and creative thinking*. Founded by E. Paul Torrance in 1974, the education program uses a six-step Problem Solving Model based on the Osborne-Parnes Creative Problem Solving Model. E. Paul Torrance promoted positive futures through the construct of creative problem solving. Organized geographically as local FPSPI affiliates, participants select one of four competition components that include Global Issues Problem Solving, Community Problem Solving, Scenario Writing, and Scenario Performance. Students prepare annual topics throughout the school year with qualifying competitions leading to the next level. At the end of the school year, a four-day International Conference (IC) hosts

champions during a culminating competition organized as Junior (grades 4–6), Middle (grades 7–9), and Senior (grades 10–12) divisions. Participants address a Future Scene as a hypothetical situation set 20–30 years in the future such as Antibiotic Resistance (2022) and Neurotechnology (2021), and participants receive constructive feedback from trained evaluators. The Global Issues Problem Solving (GIPS) component challenges participants to design positive futures, apply the six-step Problem Solving Model, and create a detailed Action Plan. Possible futures emerge as participants (1) Identify Challenges, (2) Select an Underlying Problem, (3) Produce Solution Ideas, (4) Generate and Select Criteria, (5) Apply Criteria, and (6) Develop an Action Plan.

Keywords

FPSPI · E. Paul Torrance · Creativity · Creative problem solving · Futuristic thinking · Giftedness

Identifying Challenges

As creativity evolved from a unitary to factorial conception in the twentieth century (Guilford 1950), psychologists and educators increasingly integrated definitions, models, and processes of creative productivity into P-12 school environments to develop giftedness, talent, and creativity. For example, the 1971 *Education of the Gifted and Talented – Volume I: Report to Congress* known as the Marland Report responded to the 1970 Congressional Public Law 91-230, Section 806 mandate for a status report on education of the gifted and talented in American schools. The United States Commissioner of Education Sidney P. Marland conducted the study that comprised a review of research, analysis and development of data bases, public hearings, studies of representative programs, and review and analysis of American educational delivery systems for the gifted and talented. The Marland Report concluded specialized services for the

gifted and talented make a difference and outlined 10 major initiatives.

Of significance to the founding of Future Problem Solving (FPS), the Marland Report (1971) defined children with high performance capacity through six categories that included “creative or productive thinking.” This landmark report advocated for the development of intellectual and creative abilities that would otherwise languish, especially for children and adolescents from underserved populations. The Marland Report recognized the need for evidence-based professional development on creative productivity. Guilford developed convergent and divergent tests to measure nonintellective abilities, and adaptations of these tests measured creativity in children and adolescents. When Torrance, Getzel, Jackson, and others reported differences between highly intelligent and creative populations, the resulting debate stimulated research studies on creativity measurement. Terminology shifted from creativity used as a global concept to labeling that accurately distinguished creativity and divergent thinking (pp. 35–36). Compelling evidence from studies on fluency, flexibility, and originality tests showed significant gains in divergent thinking. School interventions emphasizing creative behavior and problem solving benefitted students with giftedness (pp. 73–74). By underscoring possibilities in Gifted Education, the Marland Report set the stage for creative or productive thinking with specialized school programs such as FPS in the 1970s and sustained advocacy efforts in the 1980s. The process of exploring possible paths in creative productivity research yielded solutions with the capacity to transform the possible selves of gifted students as they encountered creative educational interventions designed to enhance their possible futures.

Underlying Problems

Ten years after the release of the Marland Report, experts in the field of Gifted Education identified 15 prevalent issues known as the “1982 Myths” that emerged during a turbulent decade in American society and education (Treffinger 2009).

A special study published in the *Gifted Child Quarterly* 1982 winter issue aimed to demythologize misconceptions; stimulate discussion, critical thinking, and creative research; and establish direction for productive inquiry and practice. Examples of these myths conceptualized the gifted as a single, homogenous population; creativity as a construct too difficult to measure; the sufficiency of one educational program for all students; and Gifted Education considered synonymous with a program (pp. 229–230). This groundbreaking article accompanied societal shifts that occurred during the 1980s “Me Generation” decade. Accordingly, advocacy efforts in Gifted Education transitioned from program development to inclusion of underserved populations, identification bias, the achievement gap, twice-exceptionality, and social and emotional needs. National educational priorities targeted science, technology, engineering, and mathematics (STEM) and rigor in core academic subject curricula and instruction. Possibilities for excellence flourished with twenty-first Century Skills considered the “new basics,” Jacob K. Javits Act funding, and emphases on differentiation, individualization, and learning styles (pp. 230–231).

Produce Solution Ideas

Sandwiched in the Zeitgeist between the Marland Report and 1982 Myths milestones in Gifted Education, E. Paul Torrance (1915–2003) founded Future Problem Solving in 1974 to address complex real-world issues during academic competitions for students in grades 4 through 12. Torrance grew up on a 700-acre family sharecropper farm that grew cotton, peanuts, and fruit trees in rural Georgia (Hébert et al. 2002). Though a precocious youngster, Torrance lacked physical strength and aptitude for the chores and responsibilities expected of him to support the family farm. During his primary school years, however, Torrance established himself as an avid reader and imaginative writer. During middle school, Torrance gained support from teachers who recognized his academic abilities, and he received awards in

writing contests. A turning point occurred when his father acknowledged his son's incapacity as a farmer and accepted Torrance's need for a college education. After graduating from high school, Torrance entered Georgia Military College where he worked in the college library, gained respect from his teachers, and enjoyed French studies (pp. 12–14). Despite his family's poverty, economics of the Great Depression, and world events preceding World War II, Torrance attained academic distinction during junior college preparation with possibilities that suited his future as a teacher.

In 1937, Torrance taught French, Latin, algebra, and history at Midway Vocational High School near his hometown and took education courses through correspondence studies (Hébert et al. 2002). After graduating from Mercer University in 1940 with honors and a BA in English and minors in history and education, he pursued counseling psychology at the University of Minnesota and graduated in 1944 with an MS in educational psychology. He taught at Georgia Military College where he developed their counseling guidance program until 1944, when he took full-time employment counseling disabled veterans at the University of Minnesota and began PhD studies. When drafted into the US Army in 1945, his physical disabilities prevented active combat. However, he worked as a psychiatric social worker and psychologist using the Rorschach Inkblot, Bender Gestalt, and Army Individual Intelligence tests. In 1946, Torrance accepted a position at Kansas State College in the Counseling Bureau for Veteran's Administration and a subsequent appointment as Dean of Men. Torrance acquired professional development skills in psychodrama and sociodrama with Jacob Moreno at Kansas State College who encouraged Torrance to pursue doctoral studies. After completing his PhD at the University of Michigan in 1951, Torrance researched characteristics on jet aces during the Korean War in his position as the Director of Survival Research in the US Air Force Training Program. His earlier experiences teaching difficult students in Georgia, counseling disabled veterans, and research studies on jet ace fighter pilots converged conceptually

with shared characteristics of “wild colts” who survived using productive creativity with varying degrees of success. Torrance identified creative skills and risk-taking as essential elements of productive behaviors and extraordinary accomplishments (pp. 14–17). He published results on survival and stress responses to emergent conditions and developed a “survival” definition of creativity as “whenever one is faced with a problem for which he has no practiced or learned solution, some degree of creativity is needed” (p. 17). Torrance viewed possibilities of human potential through the lens of creativity and survival research.

Generate and Select Criteria

Concurrent with Torrance's development as an educational psychologist specializing in creativity research during the 1950s, Alex F. Osborn (1888–1966) applied groundbreaking creativity techniques developed through his leadership in the award-winning Batten, Barton, Durstine, and Osborn (BBDO) advertising agency headquartered in New York City with branch offices around the world. In 1953, Osborn developed the brainstorming technique to generate high-quality ideas of going for quantity, withholding criticism, welcoming wild ideas, and combining and improving ideas steps. Osborn found it “easier to tone down a wild ideas than it is to think up a new one” (CEF 2014, p. 2), and brainstorming comprised part of his seven-step Creative Problem Solving framework published in *Applied Imagination* (Osborn 1953). The CPS seven-step model included the following: (1) Orientation: Pointing up the problem; (2) Preparation: Gathering pertinent data; (3) Analysis: Breaking down the relevant material; (4) Hypothesis: Piling up alternatives by way of ideas; (5) Incubation: Letting up to invite illumination; (6) Synthesis: Putting the pieces together; and (7) Verification: Judging the resultant ideas. During the next decade, Osborn consolidated the seven stages into fact-finding, idea-finding, and solution-finding stages in CPS Version 1.1 (Firestien 2017). To disseminate best practices and the

advances in creativity studies, Osborn established the Creative Education Foundation (CEF) in 1954, and the Creative Problem Solving Institute in 1955, both housed at Buffalo State College in the State University of New York. In 1966, Osborn collaborated with educator Sidney Parnes (1922–2013) on the five-stage Osborn-Parnes CPS approach to enhance student capacity to apply personal creativity through all aspects of their lives. As Osborn's successor, Parnes founded the International Center for Studies in Creativity in 1967 to teach, develop, and research creativity studies. The CEF founded the *Journal of Creative Behavior* in 1967 to publish original and innovative research, theory, and application studies. The Center for Applied Imagination ([n.d.](#)) at Buffalo State College offers Graduate Certificate and Master of Science degree credential programs in Creative Studies for educators, trainers, and consultants with virtual and on-campus options with Buffalo State College, Netherlands, and China locations. As a man of great vision and imagination, Osborn generated and selected cutting edge criteria from the advertising world to enlarge possibilities in the field of higher education.

Apply Criteria

The Future Problem Solving program emerged just 2 years after Marland introduced his study on gifted and talented to the 92nd Congress. Although individual states adopted variations of the Marland definition of giftedness, recommendations remained unfunded until the Jacob K. Javits and Talented Students Education Act of 2001. This meant inconsistent, if any, identification of gifted and talented children and adolescents, particularly among underserved populations. Specialized teacher training programs, in-service preparation for teachers and support staff, and pilot programs lacked funding earmarked for Gifted Education. In 1966, Torrance returned to Georgia with his wife Pansy where he served as Professor and Chair of the Department of Educational Psychology, Research, and Measurement at the University of Georgia until his retirement in 1984. During his

tenure at the University of Georgia, he developed the *Torrance Tests of Creativity* (TTCT) (Torrance 1966), founded Future Problem Solving (1974), developed the Incubation Model of Teaching (Torrance and Sisk 1997), and established the Torrance Center for Creative Studies in 1984. Despite the increase in creativity research, Torrance perceived a decline of creativity in American schools and society (Hébert et al. 2002). When a local high school asked him to work with gifted students, he field-tested an idea inspired by the Osborn-Parnes CPS approach combined with futuristic thinking. After experiencing the first Future Problem Solving Bowl in Athens, Georgia, enthusiastic participants requested more activities. Torrance and his graduate students planned a second competition with other school participating throughout Georgia. In 1976, the renamed Future Problem Solving Program (FPSP) offered practice activities in October, November, and February with a scenario writing contest in January. Elementary, middle, and high school students competed in April and received merit certificates of excellence. Former graduate students established FPS programs in their new locations after graduation and sanctioned programs included 29 states and the Australia-New Zealand FPS by 1988 (pp. 30–31). Applying the Osborn-Parnes CPS approach to real-world problems set in the future made creative productivity possible in academic programs as a nationally recognized interscholastic competition.

Develop an Action Plan

As Future Problem Solving Programs established state and national affiliates, the nonprofit Future Problem Solving Program International (FPSPI) organization, headquartered in Melbourne, Florida, provided oversight with International Office staff, Board of Trustees, and Board of Advisors. FPSPI maintains the mission and objectives, components, and processes of the Future Problem Solving Programs. The mission statement *develops the ability of young people globally to design and achieve positive futures through*

problem solving using critical and creative thinking, as articulates Torrance's combined focus on CPS and futuristic thinking. FPS transforms the possible selves of participants by operationalizing the six-step model to research possible pasts and imagine possible futures. Eight goals reflect his teaching experiences with diverse secondary students, counseling disabled veterans, developing assessment instruments, and researching jet ace pilots during his productive career. FPS goals provide students opportunities to increase global awareness and interest to impact their future; explore and problem solve complex, societal issues; develop, utilize, and improve research techniques; learn and apply problem-solving strategies; expand and enhance creative and critical thinking skills; engage in real-life problem solving; develop teamwork skills; and improve oral and written communication. Torrance adapted the five-step Osborn-Parnes CPS approach as a

student-friendly six-step FPS model: (1) Identify challenges in the Future Scene; (2) Determine the underlying problem; (3) Produce solution ideas to the underlying problem; (4) Generate and select criteria to evaluate solution ideas; (5) Evaluate solution ideas and determine the better action plan; and (6) Develop an action plan. The Four Cs form the cornerstone of the FPS process: creativity, critical thinking, communication, and collaboration. Collectively, the six-step model helps students develop critical and creative thinking, problem-solving, and decision-making skills.

Early Future Problem Solving Programs applied academic skills across the curriculum, complex thinking skills, and socio-emotional development for individual and team competitions supported by training and social events for students, coaches, and parents (Hébert et al. 2002). Annual FPS components offered students variety and choice based on their interests, skills, and resources. The original

F

Future Problem Solving, Fig. 2 International Conference Coach and Team Members

FPS component, Team Problem Solving, challenged local participants to collaboratively research two Practice Problems, apply the six-step FPS to an imagined Future Scene as a Qualifying Problem, and compete in an Affiliate Bowl/Final Problem. Champions from the Affiliate Bowl advanced as competitors at the International Conference. FPS now offers four competitive components that include Global Issues Problem Solving (formerly Team Problem Solving), Community Problem Solving, Scenario Writing, and Scenario Performance. Affiliates may compete as teams or individuals in Global Issues Problem Solving and Community Problem Solving components whereas Scenario Writing and Scenario Performance participants compete as individuals (see Figs. 1, 2, 3, and 4). Global Issues, Scenario Writing, and Scenario Performance components feature annual topics that participants research from business and economics, social and political, and science and technology strands. In Community Problem Solving, students identify and develop topics at local, state, national, or global levels in civic and cultural issues,

education, environment, health concerns, and human service as an area of concern. Affiliate teams and individuals compete in junior (grades 4–6), middle (grades 7–9), and senior (10–12) divisions, and Global Issues includes an adult team division. Students help select annual FPS topics submitting ideas and voting on future topics. Topics in Northern Hemisphere affiliates update on July 1, and Southern Hemisphere topics update on January 1 to coincide with their respective academic school calendar years (FPSPI n.d.). International Conference Antibiotic Resistance (2022) and Neurotechnology (2021) topics challenged competitors to explore possible futures in the four competitive components (see Table 1).

Future Problem Solving Programs include noncompetitive curricular components with Action-Based Problem Solving, Problem Solving Experience Curriculum, and Problem Solving Across the Curriculum materials. Younger students may work independently in small groups or with teacher guidance with Action-Based Problem Solving integrated as hands-on authentic

Future Problem Solving,**Fig. 3** International
Conference Variety Show

F

learning activities in regular classroom curriculum. The Problem Solving Experience Curriculum provides comprehensive curriculum at the primary level and up through grade nine as a semester course or over one to four academic years with cross-curricular possibilities. Problem Solving Across the Curriculum provides 20 years of previous Future Scenes from the Global Issues Problem Solving component for younger or older students to practice and apply the FPS process and write Future Scenes. FPS Academy Virtual Lessons support asynchronous online lessons for current annual topics. FPSPI provides curricular resources to support knowledge and skills in each component and offers virtual learning support for collaborative team work on annual topics through a partnership with the interactive Renzulli Learning management system. FPSPI aligns component curricula with state and national education standards (FPSPI n.d.). FPS academic competition and noncompetitive possibilities flourished

during the decades since Torrance conceived a futuristic solution to infuse creative productivity in schools and societies.

Possibilities for the Future

Glăveanu (2018) described the human capacity to transform past and future realities by living within the possible as an adaptation to continuously changing physical and social environments. Torrance compared future possibilities to satori awakenings as creative minds adapted to future realities (1979). Studies in possibilities require looking for solutions with the expectation of finding good results. As participants complete FPS steps, they develop critical thinking, creative problem solving, collaboration, and communication skills to create positive futures. Seemingly disconnected events, people, and concepts curiously offer possibilities as life events connect with productive

Future Problem Solving, Fig. 4 Grand Champion Bulldog Patrol Poster, Flagler Palm Coast High School, Florida

results (see Fig. 5). Torrance valued future studies as seriously as studying possible pasts to cope with unforeseen challenges, imagine possibilities, and gain new skills (Torrance 1974). He believed talking about possible futures began with everyday problems and included the possibility of solutions for complex problems. Viewing his young son physically unsuited for rural farm life, Torrance's father envisioned a promising academic future for E. Paul Torrance. Similarly, his schoolteachers nurtured his intellectual potential by offering him writing competitions and encouraging postsecondary education. Despite his inability to serve in army combat, Torrance found a niche aligned with his natural abilities and aptitudes counseling disabled veterans and administering psychological tests. As he gained new skills, Torrance advanced his professional capacity as an educator and psychologist. He foresaw possibilities as a creativity researcher that required doctoral studies, and he worked to attain

his PhD, despite limited financial resources. He perceived creativity in "wild colt" students and risk-taking jet aces as they successfully negotiated difficult or dangerous environments. Torrance countered his adverse circumstances when he imagined possible opportunities using creative problem solving and futuristic thinking.

After Torrance returned to his home state of Georgia at age 51, he accomplished his most significant life work in creativity research (see Fig. 6). Working with high school gifted students provided the catalyst to combine CPS and futuristic thinking in rigorous academic experiences to advance creative productivity. As FPS programs spread throughout the United States and 14 countries, more than a quarter million students benefited from the knowledge, skills, and dispositions gained during academic competitions. Researchers provided evidence on the effectiveness of FPS Programs to accomplish its mission by designing and achieving positive

Future Problem Solving, Table 1 International competition topics 1974–2022

Academic Year	Practice problem 1	Practice problem 2	Qualifying problem	Affiliate bowl	International conference
1973–1974	Rejecting authority	Attacks on automation	Rehabilitating criminals	Rejection of competition	Immunization against Disease
1974–1975 ^a	Knowledge explosion	Mental stress	–	–	–
1975–1976 ^a	Changing gender roles	Job mobility	–	–	–
1976–1977 ^a	The cooling of the Earth	Jobs for all	–	–	–
1977–1978	No fight! No competition!	Future water shortages	World hunger	Many ways of doing things	Computers in an Information Society
1978–1979	Underwater colonization	Space colonization	An older population	Invention and high technology	–
1979–1980	Transportation	Space travel	Ocean farming	Hypnosis and psychic energy	Alternative Energy Sources
1980–1981	Solar energy	Transportation	Home computers	Hunger and malnutrition	Increasing Longevity
1981–1982	Child abuse	Extrnormal mental powers	Drug use	Endangered wildlife	Space Colonization
1982–1983	UFOs	Ocean communities	Robotics	Pet overpopulation	Computers
1983–1984	Electronic games	Prisons	Lasers	Nuclear waste	Genetic Engineering
1984–1985	Drunk driving	Nuclear war	Education	The greenhouse effect	Industrialization of Space
1985–1986	Endangered species	Feeding the world	Artificial intelligence	American legal system	Organ Transplants
1986–1987	Garbage	Changing family structures	Water	Illiteracy	The Impact of the Media
1987–1988	Space travel	The elderly	Acid rain	Immigration	Birth Defects
1988–1989	Energy sources	Youth and the law	Nutrition	Employment	Terrorism
1989–1990	Shrinking tropical forests	The arms race	Poverty	Medical advances	Crime
1990–1991	High school dropouts	Ozone depletion	Transportation	Censorship	Corruption in Government
1991–1992	Space exploration	Legal epidemic	Sports ethics	Land use	Advertising
1992–1993	Stress on students	Hunger	Oceans	Drugs	Nuclear Waste
1993–1994	Robotics	Antarctica	Extinction of animals	Space law	Control of Disease
1994–1995	Cities	Homelessness	Kids and violence	Prejudice	Privacy
1995–1996	Firearms	Mental health	Twenty-first-century marketplace	Cybernetics	United Nations
1996–1997	Homes of the future	Extraterrestrial life	Cashless society	Competition	Increasing Life Span
1997–1998	Natural disasters	Freedom	Women in the workplace	Nontraditional families	Medical Ethics
1998–1999	Under the sea	Computer error	Education: Lifelong learning	Prison alternatives	Distribution of Wealth

futures for its participants who practice critical and creative thinking skills. FPS participants transform their possible selves into futuristic and divergent thinkers who collaborate with team members as effective problem solvers and analytical researchers. FPS participants gain expertise as innovators, ethical leaders, and global citizens (FPSIP n.d.) as they remember

the past and envision positive future realities. Annual future topics, the six-step problem solving model, and competition component outcomes equip participants to “live within the possible” (Glăveanu 2018, p. 519) as they creatively transform into their possible selves during academic events at local, state, regional, and international levels.

Abstract

The concept of “future selves” merges two terms, the “future” and the “self,” each brings a wide range of meanings, and together they offer further meaning and a focus for applied scientific fields such as cognitive sciences, social psychology, and futures studies.

The self is the object of the self-perception, the metacognitive skill that allows the person to consider themselves. The self is conceived by the individual as well as is influenced by social interactions and involved in the sociocultural processes of identity building, in which a “dialogical self” takes position in the “society of selves.”

The future is “what is going to happen” according to the Merriam-Webster dictionary, but much more from the perspective of futures studies. The future is the domain of predictions, hopes, plans, fear, and anxiety, a domain of possibilities, as opposed to past and present realities. The future is the necessary reference for any description of a social entity and a dimension of human existence.

The “future selves” are representations of oneself in the future, recently regarded as the foundation of human action in terms of anticipatory behavior or explicit foresight.

This entry starts with the definitions of future selves in a variety of fields, mentioning some recent applications. Then, it focuses on the relation between future selves and the

future consciousness. The conclusions present some reflections on the role of future selves in the development of the capacities of individuals and communities, in the context of future literacy.

Keywords

Anticipation · Agency · Future consciousness · Temporally extended self · Futures literacy · Possibility thinking

Research on Future Selves

The term “future selves” can be considered an evolution of the concept of “possible selves,” presented as conceptions of ourselves in future states, in relation between motivation and social cognition (Markus and Nurius 1986). The conceptions of our selves are related to what we want to be or fear to be and work as a mediating link between motivation, guiding our behavior, and our social and cultural understanding of the world around us (Dunkel and Kerpelman 2006). Erikson argues that possible selves include an experience of what it would be like to be in the future state in question; thus, possible selves, as a theoretical construct, should be seen more distinctly as a part of the self and not in isolation as just a representation of the future (Erikson 2007).

Future selves can be understood as possible alternative evolutions of a “temporally extended self” (TES), and their variety and quality affect self-esteem and play a role in determining motivation and behaviors in pursuing a goal. Understanding the way how people envision and view their future selves matters for predicting their effect. Unlike the past, people anticipate *becoming* whatever they forecast for the future. This underpins the importance of how one envisions their future: Their conclusions may affect self-regulation and behavior in a myriad of ways. The psychological time distance from a future self has been shown to affect current identity, motivation, and goal-directed behavior. Our future selves can deflate or flatter us, motivating or demotivating to achieve hoped-for selves (Peetz and Wilson 2008).

This resonates with Rosen's concept of anticipatory system (Rosen 2012): "a natural system that contains an internal predictive model of itself and of its environment, which allows it to change state at an instant in accord with the model's predictions pertaining to a later instant." This theory provided the conceptual foundation for foresight studies (Louie 2010).

Many researchers investigated how future self-predictions influence on personality, motivation, and agency (Hoyle and Sherrill 2006; Lazaridis and Bauer 2013; Leondari et al. 1998; Oettingen and Mayer 2002). Positive possible selves may be an enabler of depression-coping skills, while negative possible selves are associated with depression and anxiety (Mathews et al. 2020; Penland et al. 2000). The self-recognition has a role in preschoolers' performance on tasks requiring memory, attention, inhibition, and planning; the self becomes the ultimate executer of behavior (Ross 2008). Lazaridis and Bauer provided an interesting study exploring when children develop a temporally extended self and about which factors contribute to its development, revealing that the caregiver conversational style was the only factor that contributes to the children's metarepresentational ability in the understanding of their TES (Lazaridis and Bauer 2013). TES seems emerging in reciprocal social interactions and affective engagement (Zocchi et al. 2018), supporting a conception of the self as a dialogic entity related to alterity (Hermans 2019; Zahavi 2015). Such a dialogical entity includes a variety of selves, with "internal and external positions," and implies that society is not merely the environment of the self but its complex and multi-dimensional element (Hermans 2019).

The self-identity relies on a self-narrative that provides a sense of continuity with the past, and based on this past, it also projects out into the future, providing an anticipated trajectory for the person into the future; connecting the past, present, and future gives coherence and meaning to a person's life. Without this sense of continuity, there is no future (Damasio 1999). The future consciousness as a multifaceted capacity is considered the most critical ability needed for the survival and growth of humanity and the

flourishing of the individual (Lombardo 2009). Thomas Lombardo has published several books and articles on this topic and considered future consciousness as "the total integrative set of psychological abilities, processes, and experiences humans use in understanding and dealing with the future" (Lombardo 2006). We could say that self-identity and future consciousness are connected through future selves.

The complementary (or oppositional) drivers toward stability, security, and certainty versus growth, risk, and adventure are essential to future consciousness and make it highly adaptive, especially in a world of rapid change. People can be reactive or proactive about their actions. Proactive approaches are tied to the internal locus of control, so they depend on individual qualities such as self-efficacy and perceived competence upon which future selves are conceived. Reactive approaches, which often entail fear or anxiety, put control in the world and rarely allow for an internal clear representation of future selves.

Interesting reflections concern the relationships between the future selves and the others. The decisions people make for future selves and other people are similar to each other and different from their decisions for present selves (Pronin et al. 2008). Le Morvan (2009) argues that selfishness and altruism can be interpersonal and intrapersonal, suggesting interesting frames in economic and psychological studies. Interpersonal altruism and selfishness imply diverging effects of actions on different interests; in other words, when the interest of others diverges from one's own, acting altruistically involves acting to promote the interest of others at cost to one's own interest, whereas acting selfishly involves acting to promote one's own interest at cost to that of others. The intrapersonal altruism and selfishness rely on a temporal distance between present selves and future selves; where there is a divergence between the self's interest at the present and its interest in the future, the self can act to promote its present interest at cost to its future interest (intrapersonal selfishness) or its future interest at cost to its present interest (intrapersonal altruism). Le Morvan offers thought-provoking examples such as the Eager Eater and the Meagre Eater, the

Procrastinator and the Early Bird, the Sun-Bather and the Sun-Avoider, and The Exercise-Avoider and the Exerciser; the former of each couple take actions to satisfy their interests in the present at the cost of their interests in the future (Le Morvan 2009).

The Future Selves and the Possible

The negative and positive future selves, the intelligibility of future selves, are related to the definitions of ► **adjacent possible**, as “*the set of possibilities available to individuals*” (in Björneborn 2020), in which new possibilities may be limited or developed, according to the constraints of the agents or of their environments and their capacities and affordances. This notion can be associated to the notion of ► **potential**, as “something that can develop or become actual,” which has acquired a fundamental role in the realm of creativity studies (Runco, Lubart, etc. in Corazza 2020). In such an interpretation, the individual or collective creativity expands the possible with innovation and novelty in both convergent, goal-directed, ways, and in divergent, exploratory and serendipitous, ways (see ► **“Divergent Thinking”**). Here it is interesting to note that increasing the temporal breadth considered in the future thinking facilitates the creative thinking (Chiu 2012). On the other hand, a ► **creative mindset** implies opening oneself to apparently illogical but generative considerations, such as contemplating an event both impossible and possible at the same time, instead of simply labeling reality with the binary category impossible or possible (Karwowski 2020).

Creative abilities and qualities are valued in the field of education, underpinning the concept of ► **possibility thinking** (Lin 2020) associated to the “transformation from what is to what might be, in everyday contexts for children and teachers” (Craft et al. 2013; Craft and Chappell 2016). According to Craft and her colleagues, the skill in possibility thinking involves self-determination and intentional action, being imaginative, and collaboration. In turn, the self-determination and intentional action are resumed

in the concept of *self-direction*, which means “making [one’s] own decisions and managing one’s own work” (Cambridge Dictionary) and depends on self-competence and self-esteem. In general terms, living within worlds of possibility and intentionally developing possible selves is the ontological condition of human beings, a question deeply explored in psychology.

Possibility thinking is associated to “future thinking” that refers to the imagination of possible future events or one’s ability to creatively imagine the limitless possibilities of hypothetical future scenarios (Chiu 2012). The orientation to the possible (or to the future) simultaneously refers to person-related and contextual properties and relies on three major psychological processes, motivation, planning, and evaluation. In such an orientation, individuals move into the past through the use of memory and imagine the future, developing their own mental representation of the future; such ability is defined as “future time perspective” (Husman and Shell 2008). Causal attributions and expectations concerning the future play an important role in this evaluation. When adolescents explore future opportunities, set goals, and realize them, they simultaneously develop their own identity (Nurmi 1991), and their future time perspective has a role in career decision-making (Walker and Tracey 2012). Besides, the development of future orientation depends upon the socialization (Trommsdorff 1983). From an anthropological perspective, the future is a dimension of human existence, where some reference to the future is necessary to the description of any social entity, “where there is no future there is no social organization either” (Sande 1972).

Developing Future Selves in a Common Ground: From Future Consciousness to Future Literacy

The future is the domain of predictions, hopes, plans, fear, and anxiety, a domain of possibilities, as opposed to the past and present possibilities, for individuals as well for groups and communities. Throughout history, the future has almost always

been considered in forecasts by “experts,” in the modern age especially in the field of economics and military studies; according to Øystein Sande, the today task of futurology is to democratize the future and make it a political subject for people and communities (Sande 1972). The Polak’s concept of future as a driving force (Polak 1973) stimulated a variety of reflections on the nature and historical development of the human capacity to think about the future.

According to Lombardo, bringing future consciousness into education and popular culture becomes a critical challenge especially for our times, “The more complex the world becomes, the more we need future consciousness to evolve” (Lombardo 2006, pp. 61–67). Constructively heightening future consciousness implies the development of important human virtues and skills, such as understanding the big picture of the future, self-responsibility, courage, optimism, and transcendence or the capacity to identify with something of great value or importance beyond oneself (Lombardo 2009, 2016). Summarizing all these, future consciousness itself is considered a virtue, the main feature of wisdom, and even a dimension of human excellence that contribute to authentic long-term happiness, as defined by Seligman, in opposition to the short-term superficial happiness (Seligman 2002).

Recently, future consciousness is interpreted as a “shared capacity” and as “awareness of the future potential of the present moment,” limited by cognitive, psychological, and systemic issues. Sharpe and Hodgson identified three modes of anticipatory awareness, short-term “managerial,” midterm “entrepreneurial,” and long-term “visionary,” that represent foundational forms of future consciousness (Sharpe and Hodgson 2017); in their Three Horizons method, future consciousness can be thought through the explicit use of all three perspectives (Sharpe et al. 2016).

Ahvenharju and colleagues, through literature review, have gathered a variety of future consciousness characterizations, arriving to define five dimensions of futures consciousness: time perspective, agency beliefs, openness to alternatives, systems perception, and concern for others (Ahvenharju et al. 2018). Their model addresses

the relevant question about what an entity needs to do to have in order to have a high level of futures consciousness. The entity in question may be an individual, a group, an organization, a nation state, or perhaps, humanity overall.

It is worth to note that future selves are linked to all the five dimensions. “Time perspective” is about understanding the concept of passing time, which is the basic prerequisite for being conscious about the future; interestingly, the authors use “time perspective” rather than “future perspective,” to put on together all three aspects of time: past, present, and future. Bearing in mind this dimension, a person can distinguish a variety of future selves over time, enabling her time perspective (see the concept of “temporally extended self”) with different ability according to the length of timing extension; thus, the variety of future selves could be poor and compressed within a short period (for example, a few months) or rich and extended in possibilities (for example, over a decade).

The “agency beliefs,” which is the sense of being able to influence how the future will unfold, is the dimension associated with the abovementioned psychological topics such as self-direction, motivation, and self-esteem. In this dimension, future selves could be “ineffective” or “effective” along a gradient of agency, distinguishing the different attitudes toward the future into five categories defined by Godet: passive, reactive, preactive, proactive, and anticipative (Godet 2006).

The “openness to alternatives” combines creativity, imagination, and critical thinking in the “capability of embracing and appreciating change, seeing the value of alternative ways, and questioning established truths” (Ahvenharju et al. 2018). Considering this dimension, future selves could be closed or open to their potential with their own originality, or they could simply conform to mainstreaming definitions of the possible future (likely the most probable and repetitive one).

The “systems perception” entails a systemic and holistic thinking underpinning an open systems approach with open anticipatory assumptions rather than viewing systems as closed,

deterministic, and controllable. Miller and colleagues assert that the former is more appropriate for taking into account human agency and emergent novelty: A person focused only on partial systems would be less able to understand the complex and long-term consequences of her decisions (Miller 2019). This implies future selves are regarded as part interacting and interdependent with a variety of systems, and they could vary from being subject at the mercy of linear processes to being agent within complex interactions and consciously “dancing with systems” (Meadows 2008).

The “concerns of others” implies the values, morals, and ethical thinking associated with the desirability of possible futures or of what a person wants to see realized in the future. Groves argues that our responsibilities toward future people are of urgent importance in a period of increasing number of intrinsically unknowable technologically produced risks; the individual responsibility toward the others and the future people follows the human beings as primarily relational rather than individualistic (Groves 2009, 2017). In this dimension, future selves could range from inspiring and enacting that responsibility to pursuing an individualistic desirability.

In brief, the Ahvenharju and colleagues’ model of future consciousness consists of three actor-centered dimensions (time perspective, agency beliefs, and openness to alternatives) and combines them with two dimensions that focus on the larger societal level (systemic perception, concern for others); all these dimensions underpin the variety of future selves as well as depict the processes to enrich the development of future selves.

A recent study has shown that these dimensions can be improved by future-oriented education (Chen and Hsu 2020). Anyhow, future consciousness is present in everyday anticipatory behavior (see ► [“Anticipation”](#)) and explicit ► [foresight](#), underpinning the effort to build images of possible, probable, and preferable futures and paths to such futures. Such ability to imagine and influence tomorrow is a foundation of futures literacy.

According to Riel Miller (UNESCO Chair in Futures literacy), this is the “capability, the skill

that allows people to better understand the role of the future in what they see and do. Being futures literate empowers the imagination, enhances our ability to prepare, recover and invent as changes occur” (Miller 2019). The futures literacy is considered as an “essential competency for the twenty-first century,” and it is stimulating a growing worldwide community, the Global Futures Literacy Network, including futures researchers, practitioners, and supporters, spanning across the globe, in academic and government institutions, as well as businesses and NGOs (UNESCO 2020).

From this community, an increasing number of experiences and reflections is emerging, especially related to education and teaching. Häggström and Schmidt situate futures literacy in a multifaceted pedagogy (Häggström and Schmidt 2021), in which the future selves can be imagined by the child while acting as an agent of change and feeling kinship with other human beings as well as with the other-than-humans. Pouru-Mikkola and Wilenius structure parallels between futures education and futures literacy theories and propose a conceptual model for “transformative futures learning” that contains the key components that construct futures capacity in an individual: cognitive, motivational, and active dimensions of using the future (Pouru-Mikkola and Wilenius 2021).

Summary

Future selves are an important part of our individual identity, a temporal extension necessary to motivate our actions and give meaning to our life and our plans, but despite all this they are not merely private. As we are relational beings, future representations of ourselves are also relational entities that influence and are influenced by others.

The future selves can be “locked up”, compressed into a short time horizon, lacking in creative abilities, self-centered, at the mercy of processes perceived as deterministic, or “freed,” varying in vast temporal horizons, and confident of being able to influence future conditions but at the same time open to alternatives and in empathic

connection with others. Considering how we define our future selves is meaningful to us and to our communities; cultivating freed future selves requires a capacity for metacognition, thinking about how we think, how we define ourselves, and what drives our decisions, all skills that can be learned throughout life.

Future selves should be at the focus of future consciousness and futures literacy in order to bridge the personal futures and the global/collective futures; mentioning Lombardo, through the enhancement of future consciousness we facilitate the development of more ethical human beings (Lombardo 2009). Remembering Bell's teachings (Bell 1998), as people learn to search for possible futures (including future selves) more fully, to forecast probable futures more accurately, and to make judgments of preferable futures (and future selves) more ethically, they can become more responsible actors, i.e., active, purposeful, and innovative beings whose future-oriented behavior helps create not only their own future but also the social order itself.

Alternative Planetary Futures Institute (ApFi),
Washington, DC, USA

Keywords

Futures Studies · Foresight · Big Space · Big Time · World Futures Studies Federation (WFSF) · Sustainable Development Goals (SDG) · Alternative Planetary Futures

Definition

Futures studies is an art and a science with a strong emphasis on imagination and creativity in creating different possible futures. Its main purpose is to discover and master the complex chains of cause and effect through conceptualization, systemic approach, and feedback loops, ultimately providing innovation in the social and technological fields. There is a great and important distinction between Globalization and Planetization. Political spaces can benefit a great deal if some doubt is cast on the agenda of globalization and put in its place the idea of “planetization,” a planetary consciousness or identity.

Introduction

When discussing or introducing the art and science of futures studies or if integrated with planning, strategic foresight, it is generally assumed that foresight experts intend to predict the likely future based on existing trends and evidence. But in high quality futures studies, in addition to the probable future, the desired or normative future, plausible, and possible futures are also considered (Gidley 2017). For example, how historical and current conditions can contain a consistent chain or story of potential events and surprises, and therefore, in addition to recognizing the connections with historical structures, they also seek to discover discontinuities and put an emphasis on

the importance of human agency; i.e., crossing transforming structures and challenging them. In fact, in the realm of possible futures, reference to specialized science-fiction literature in addition to popular movies is also prominent (Lombardo 2018).

One should note that there is an ongoing crisis of identity in the specialized English-speaking futures studies literature about what word or expression is more appropriate to describe the field and the profession (Sardar 2010). Although there is not yet a comprehensive agreement in the English-speaking world, there are compelling opposing arguments against the use of certain terms. The suffix – ology often is used to describe scientific disciplines such as psychology, geology, cosmology, etc., where the researcher deals with real data and fact. But futurology cannot be meaningful in this sense because of the uncertainty, or uncertainty about the future. There are only images about the possible futures and there is no fact that the researcher wants to know and thus become futurologist. The future in this respect is the realm of imagination. It is not merely processing current facts and extrapolating trends.

Conceptualization and Innovation

Professional futures studies include intellectual and practical activity that covers all key areas of life including psychology, social, economic, environment, politics, and technology. Its main purpose is to discover and master the complex chains of cause and effect through conceptualization, systemic approach, and feedback loops, ultimately providing innovation in the social and technological fields. Its scale must also be a combination of attention to planetary consciousness and national and local issues.

It is necessary to have a multidimensional perception of and reciprocity among economic, political, and human developments. Cutting edge science and advanced technologies are pushing exponential and rapid progress. On the other hand, the planetary human society because of unwise leadership in many countries is engaged in all kinds of conflicts. Because of the cultural

lag – and more importantly legal lag, the society at large cannot keep up with the technological developments and tsunami of change, and therefore communities have been caught in the whirlpool of crises.

The birth place and the well-funded programs on futures studies are often associated with the national security strategic studies centers or think tanks, which are close to the defense, intelligence, and armed forces organizations because such studies provide useful insights for identifying long-term or strategic threats (Motti 2017). But more recently in the corporate world as well as the public sector, the board of directors are also shifting the focus and agenda of their strategic planning and research and development departments to the application, implementation, and institutionalization of the science and art of organizational futures research also known as corporate foresight (Rohrbeck and Kum 2018), using professional scanning and monitoring systems to identify weak and strong signals, trends, driving forces of change, and even potential black swans or wild card events. They often deal with the systemic consequences to better make sense of transformation or collapse. It is worthwhile to note, however, that there is yet another strand of futures studies that provides a balance against the dominance of the top-down government or corporate foresight by the enlightened leaders through a more bottom-up sustainable way, which is called open participatory foresight to set policy goals and long-term strategies. The Citizen and Multi-Actor Consultation on Horizon 2020, CIMULACT Project, is among the best practices of such approaches (Rosa et al. 2021).

Futures studies is an art and a science with a strong emphasis on imagination and creativity in creating different possible futures. Major researchers are more inclined to produce text, graphs, tables, and questionnaires because of their tendency toward more positivist views and quantitative analysis, but closer communication with ordinary people and extensive educational and promotional efforts is vital because the general public generally think that futures studies is the same as accurate prediction or even worse see it as related to the power of divination.

Shedding light on the macro model of the history is a crucial mental skill too. If society has gone through stages of growth and maturity in addition to seeing news, events, and happenings, it should also sense the big picture and the trajectory of mega trends. Better identification and understanding of trends is, of course, the first step, and in the higher stages of growth and maturity, society goes through events and trends and reaches key underlying patterns of change (Halal 2021).

Big Time and Big Space

The main difference between professional futurists and analysts who try to predict or forecast the prices in the stock market is the focus on big time and big space. As for the time, one of the ambiguities is always whether it means the next month, after the next elections, or like the 20-year horizon official vision documents, or even more than 30 years later. Professional futurists emphasize that the longer the time horizon, the more relevant the future research, open participatory foresight, and co-creation with good design will be. It can be noted that in 30-year time, more novel things are possible compared to when you define your horizon for another year or the next business quarter, especially if your goal is to build a desirable future. Another important issue is to identify subsequent historical periods, eras, ages, and epochs with a diversity of theories that rely on structure, agency, or the combination of both.

In addition to the big time, one must pay attention to big space or planetary scale. Today, unfortunately, many officials and governmental planning activities have a closed and limited attitude in terms of political imagination and action. Perhaps a governor's office, when planning for the future, considers itself separate from the rest of country. Or a country sees itself as independent of the future of the surrounding region. Leading futurists practically intend to consider the big space in terms of complex and intertwined layers of planetary, regional, national, local, and organizational scales in an integrated and coherent way.

The Best Practices

The World Futures Studies Federation (WFSF), as an international scientific and nongovernmental association, is one of the leading institutions that accepts not only pluralism but also promotes the importance of big time and big space. The Federation was founded in 1973 in Paris. In other words, the history of modern futures studies spans only 50 years. The WFSF acts like an umbrella organization to embrace all the leading figures of futures studies based on the value of pluralism. WFSF also has a very close relationship with UNESCO and the program of enhancing Futures Literacy as a fundamental quality or capability to challenge the current dominant imagination about the possible futures and how to embrace and to live with complexity, novelty, and uncertainty (Miller 2018).

On the planetary scale, the issue of sustainable development is the focus of international institutions today, especially the United Nations Economic and Social Council, so much so that the set of UN Sustainable Development Goals (SDG), which include 17 ideals or possible goals, has practically become the future agenda of the better planet (Nelson 2021). Experts and activists worldwide are constantly evaluating and monitoring the indicators for measuring planetary development (Glenn and Florescu 2017).

The setting of SDGs and the associated evaluation and monitoring are admirable and necessary steps toward increasing our collective awareness about planetary conditions. The setting of goals and targets and the monitoring of indicators are all very much necessary. But mostly informed by a positivist, objective analysis of the external world, this approach often downplays the importance of measuring and monitoring the inner world transformations of each individual, shifting of worldviews, and evolution of modern mythologies.

A Different Globalization

There is a great and important distinction between Globalization and Planetization. Political spaces can benefit a great deal if some doubt is cast on the

agenda of profit- and power-driven globalization and put in its place the idea of “planetization,” a planetary consciousness or identity, and the associated goals and targets that are necessary to make a radical change in the inner world of individuals, meaning that no one will be forgotten or left behind.

The SDGs will be achieved by humans who cannot follow heartless algorithms or cold and dry instructions. The framework of a possible planetary future should integrate analytical thinking with motivational feelings. It serves to transform the inner world of individuals, as well as the world out there, by helping them to question and update their mythologies, theologies, and the underlying worldviews and values (Motti 2019).

We, therefore, need evaluation and monitoring of three key programs:

1. Culture of Hope Through Planetary Consciousness
2. Planetary Benefits and Risks of Technological Revolutions, and
3. Integral Development of Scientific Worldview in Art and Literature

There are seven valleys in a value-focused transformation of consciousness for a possible world characterized with planetary wisdom:

- 1/Question all and any natural born identities
e.g., tied to geography, ethnicity, nationality, faith, language, etc.
- 2/Love the aliens' cultures and hybrid mindsets
e.g., those of foreigners' on this planet or even extraterrestrials with the least common shared overlapping believes, norms, and practices.
- 3/Embrace the planetary identity to save the ecology
e.g., by refusing the geopolitical boundaries, to tackle climate change, loss of biodiversity, depletion of natural resources, etc.
- 4/Refuse all and any justification of violence and killing
e.g., avoid to praise warfare in texts and movies and stories and stop glorification of fighters and warriors, etc.

5/Practice the key principles of scientific worldview

e.g., obtain a mythical sense of awe and reverence in learning laws of nature governing the cosmos and practicing a global ethics that is inclusive of non-humans.

6/Realize the no-human-work economy and all activist society

e.g., support automation of undignified hard and boring labor and encourage everyday activity of political participation.

7/Transcend the simple vs. complex binary through enriching our symbolic systems

e.g., create new higher level frames or languages to enrich the big picture understanding and more simple elegant generalization of the lower level confusing complexity.

Summary

Imagination of the possible worlds might be largely facilitated if guided by the growing literature and best practices provided in the futures studies field. Although government and corporate initiated vision building and foresight exercises are playing an increasingly important role, more attention should be given to the open participatory foresight and enhancing the futures literacy. Use of the future for the purpose of achieving planetary consciousness was demonstrated by providing an outline of a different possible world through which the dominant elements of globalization are questioned.

Genetic Engineering

Elena L. Grigorenko
University of Houston & Baylor College of
Medicine, Houston, TX, USA

Abstract

This entry provides an overview of genetic engineering, which is the deliberate modification of the characteristics of a living organism by manipulating its genome. It briefly introduces some relevant terminology and presents the history and the current status of the related field of scientific inquiry. The entry concludes with a discussion of the selected ethical issues that are currently debated both by the scientific community and by the public.

Keywords

Genetic/genome editing · Genetic/genome engineering · Genetic/genome manipulation

Introduction

Since the second half of the last century, there has been a continuous effort to develop cost-efficient and reliable approaches to precisely alter the genome of living cells (Kozovska et al. 2021). The foreseeable benefits of these approaches are difficult to overestimate as they range from public health (e.g., eliminating or editing genes

responsible for specific genetic disorders) to agriculture (e.g., manipulating specific features of plants and animals to enhance their yield for human needs).

Different metaphors have been used to describe these approaches (Baylis 2019). As the human genome is often referred to as the “book of life,” the metaphor of editing is used to visualize the act of finding, cutting, replacing, and pasting parts of the genetic code. As one of the renowned scientists in the field, Jennifer Doudna puts it, extending the editing metaphor, the genome can be as “malleable as a piece of literary prose at the mercy of the editor’s red pen” (Doudna and Sternberg 2017, p. 90). Another oft used metaphor is that of engineering, which stresses the design and construction facets of this process. Yet other metaphors utilized both in scientific and popular literature are that of genetic/genomic hacking, surgery, and modification. All these terms, in general, are used interchangeably. In this entry, the term “genetic engineering” is used, which, in David Bodine’s words (<https://www.genome.gov/genetics-glossary/Genetic-Engineering>), means that pieces of DNA are isolated, combined with other pieces of DNA, and then propagated in any number of various organisms. In more technical terms, genetic engineering techniques refer to a family of biotechnologies, where DNA sequences are changed by deletion, mRNA processing, and posttranscriptional modifications to cause altered gene expression, which, in turn, results in modified proteins, and, eventually, phenotypic

changes. These techniques use nucleases or molecular scissors to intentionally introduce alterations into the genomes of living organisms (Rogers and Pfuderer 1968). These biotechnologies are unified by three basic steps, namely: (1) entry into the cell and, ultimately, the nucleus; (2) alteration of gene transcription and downstream processing function; and (3) suppressed, overexpressed, or quantitatively modified protein product (Khan 2019).

Genetic engineering first emerged in the early 1960s with the development of recombinant DNA (rDNA) technology (Szybalska and Szybalski 1962) and has rapidly progressed with the appearance of various biotechnological tools such as viral vectors (Gaj et al. 2013). The scope of the related research and practice is vast: since the end of the last century, more than 1900 clinical trials utilizing various gene engineering approaches have been carried out (Tamura and Toda 2020). These approaches rely on randomly inserted specific DNA sequences into the host genome using conventional genetic engineering tools. The beginning of this century has been marked by the rapid development of novel tools that induce genome modifications not randomly, but in a targeted manner at specific sites. Among these tools are zinc-finger nucleases (ZFNs), transcription activator-like effector nucleases (TALENs), and the recently established “clustered regularly interspaced palindromic repeats”/CRISPR-associated 9 (CRISPR/Cas9) technologies (Gaj et al. 2013). These genome editing tools are now recognized as appropriate, efficient, and effective for intentional genetic engineering; thorough and rapid research with these tools has led to the development of novel treatments for a broad spectrum of various maladies, from genetic diseases and cancers to organ failures. This entry provides a brief history of the field, selectively illustrates relevant approaches, and touches on the related ethical concerns.

History of Genetic Engineering

The history of genome engineering is extensive and demonstrates a consistent and ongoing drive

for progress (Capecchi 2005; Urnov et al. 2010). The initial proof of concept of virus-mediated gene transfer (Rogers and Pfuderer 1968) demonstrated that foreign genetic material could be transferred into cells by viruses. This work was followed up by the first human gene therapy experiment, where Shope papilloma virus was transduced into two patients with genetic arginase deficiency (Rogers et al. 1973). The therapy did not lead to improvement in the patients, and the experiment generated concerns about the risks and rewards of gene therapy. As a result of public discussion, ethical standards for the clinical application of gene therapy have been proposed (Friedmann and Roblin 1972). Yet, there were instances of unethical applications of genetic engineering (Johnson 1980), which, in turn, led to the appearance of the report of the US President’s Commission, in which a distinction was drawn between somatic and germline genome editing in humans as well as between medical treatment and nonmedical enhancement (President’s Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research 1982). With regard to the former distinction, the report stressed the importance of recognizing that the insertion of an altered gene into a germ (sperm or egg) cell triggers changes not only in the treated individual, but also in their future offspring. Changes made to somatic cells are not heritable, meaning that they are not passed on to future generations. With regard to the latter distinction, the report pointed out that genetic alterations of typical (i.e., not disordered) people are charged with the danger of “perfecting” human beings. One more important distinction differentiates the *in vivo* and *ex vivo* strategies utilized in genetic engineering. In the *in vivo* strategy, genetic vectors are directly delivered into the patients, and genetic modification occurs *in situ*. In the *ex vivo* strategy, the cells are altered *in vitro* and then are delivered back to the patient.

The 1980s were marked by the utilization of primarily nonviral methods for gene delivery (e.g., microinjection and calcium-phosphate precipitation). Although these methods exhibited some advantages over the viral ones (e.g.,

large-scale production and host immunogenicity), they also had some disadvantages (e.g., lower levels of transfection and gene expression); the disadvantages outweighed the advantages as they led to limited therapeutic efficacy (Jin et al. 2014). The field has intensified the use of viral vectors, with the first Food and Drug Administration (FDA)-approved gene therapy being performed in 1990 (Blaese et al. 1995). Initial advances in the utilization of retroviral vectors led to developments in the use of recombinant adenoviral vectors. Unfortunately, early clinical trials utilizing viral vectors produced mixed results, with a number of lethal outcomes; yet, the continuous development of the related technologies has generated some remarkable success (Tamura and Toda 2020). For example, adeno-associated viral (AAV) vectors have been utilized in more than 200 clinical trials for several genetic diseases such as spinal muscular atrophy (Mendell et al. 2017), hemophilia (Nathwani et al. 2014), and retinal dystrophy (Bainbridge et al. 2015).

Current Developments in Genetic Engineering

Early genetic engineering technologies using viral vectors to randomly insert therapeutic genes into a host genome exhibited side effects such as insertional mutagenesis and oncogene activation. The continuing development of biotechnologies was aimed at the search for techniques that permitted the intentional insertion of the desired DNA material at site-specific locations. This development led in the second decade of the twenty-first century to the creation of three types of engineered nucleases: ZFNs, TALENs, and CRISPR/Cas9. These engineered (also referred to as programmable) nucleases take advantage of natural cellular pathways of DNA repair to introduce targeted sequence modifications.

In both the zinc-finger nucleases (ZFNs) and transcription activator-like effector nuclease (TALENs) tools, DNA binding proteins (zinc fingers in ZFNs and TAL effectors, TALE, in TALENs) are fused with an endonuclease (FokI) to obtain precisely targetable nucleases (Prasad

et al. 2021). The DNA is cut, and the resulting double-strand breaks (DSB) are subsequently corrected by cellular break repair pathways that form small insertions or deletions, resulting in edited DNA. Zinc-finger domains recognize a trinucleotide DNA sequence (Kim et al. 1996). TALE proteins have multiple 33–35 amino acid repeat domains that recognize a single base pair (Christian et al. 2010). The difference between TALENs and ZFNs is that the former can target three nucleotides in one go and the latter can only address 1 nucleotide, thus making TALENs slightly more site specific with fewer off-target effects (Chandrasegaran and Carroll 2016). The techniques share many similarities, but their main limitation is in the labor and time consumed to synthesize new DNA binding proteins each time to target a new location (Kim et al. 1996). Therefore, scientists continued to look for easily programmable nucleases (Joung and Sander 2013).

Such a nuclease emerged in 2012 when it was reported that the bacterium *Streptococcus pyogenes* could be adapted for gene engineering. This system consists of the “Clustered regulatory interspaced short palindromic repeat” (CRISPR) of RNA (or, rather, two RNAs, CRISPR RNA, crRNA, and transactivating CRISPR RNA, tracrRNA [Cong et al. 2013]), which acts as a guide, and the Cas9 working as an endonuclease enabling double-strand breaks, DSBs (Jinek et al. 2012). The critical differences in CRISPR compared to previous approaches are: (1) the use of a short RNA sequence serving as the specificity-determining element for DSBs; (2) its relative simplicity, as it requires only a single guide RNA (sgRNA); and (3) it does not require the engineering of a site-specific nuclease, which is time- and money-consuming (Lino et al. 2018). Thus, the early research and development of gene engineering tools had determined that the prerequisite for any genome engineering technology is the capacity of its molecular agent to specifically bind and introduce a DSB in the target region, for subsequent correction by the cellular repair machinery. The CRISPR/Cas system fulfilled both requirements: specific target recognition by the spacer sequence and DSB by the Cas9 nuclease. Unlike in ZFNs and TALENs, target

recognition by CRISPR is mediated by the 20-nucleotide spacer sequence in the crRNA (Carroll 2014). Designing and synthesizing varying nucleic acid sequences to bind to target regions is much easier and cheaper than designing proteins for the same, thus CRISPR/Cas9 provided a simple, economical, efficacious, and versatile tool that could be made to target any desired sequence by altering only the ~ 20 bp spacer sequences (Prasad et al. 2021).

It is important to note that research into the CRISPR/Cas system had begun a long while back. It had long been known (Mojica et al. 1993) that the bacterial genome had certain sequences that repeated several times with regular spaces in between them. Mojica named these sequences CRISPR and identified them as fragments of DNA from bacteriophages that attack the bacteria; however, how and why these fragments were integrated into the bacterial genome remained unknown (Mojica et al. 2005). Jennifer Doudna of the University of California at Berkeley and Emmanuelle Charpentier of the Max Planck Institute for Infection Biology in Berlin elucidated the mechanism of the CRISPR/Cas system and developed it into a genome editing tool (Jinek et al. 2012). Their work was recognized by the 2020 Nobel Prize in Chemistry. It is noteworthy that other scientists working independently at the same time, including Feng Zhang of MIT and Harvard and George Church of Harvard Medical School, showed that CRISPR genome editing could work with mammalian cells. Thus, it took almost 20 years (1993–2012), since the discovery of the CRISPR/Cas system in bacteria, to elucidate the mechanism of its action and transform it into a gene engineering tool. Since 2012, however, the field of genetic engineering has experienced an incredible surge to perfect the technology and underscore its potential in both research and clinical practice. One of the derivatives of genetic engineering is gene therapy, which has advanced medical treatments for patients with congenital diseases and cancers. CRISPR technologies have continued to develop and are expected to continuously progress. Even though there are still many challenging obstacles to surmount to ensure their safe clinical application, these

methods signify the possibility of treatment for a wide variety of human diseases.

Ethical Issues

Genetic engineering offers opportunities for making beneficial, precise, and safe modifications in the genomes of various organisms (Chandrasegaran and Carroll 2016). Such molecular technologies are both speedier and cheaper than laborious and expensive crossing and back-crossing methods. For example, in some plant and animal genomes, such modifications have been applied to loci that provide tolerance to heat and drought. There are also examples of improvement in livestock. It is important to note that much of the current resistance to genetically modified organisms (GMO) stems from issues related to proprietary ownership and the political relationships between seed companies and crop producers. Beyond applications of the alteration of genomes to contribute to the food supply, there are opportunities to use genome-edited model organisms to understand and treat human genetic diseases. Genetic engineering has been used to grow functional human organs in model animals. There are also applications of genetic engineering to human therapy. It is important to know that various genetic engineering platforms (e.g., ZFNs, TALENs, and CRISPR-Cas9) are used for practical (e.g., agricultural and medical) applications, each of which has its advantages and disadvantages.

Genetic engineering is a powerful tool that can lead to alterations of both somatic and germline cells. Related genuine bioethical concerns have been explicated (Krishan et al. 2016). As for the public opinion, although there is broad enthusiasm for somatic cell genome editing as a future treatment for patients with inherited life-threatening or debilitating diseases, there are also important concerns pertaining to ensuring the safety, efficacy, and effectiveness of any genetic modification, as well as the accessibility of these treatments, which are currently very expensive (e.g., products by such companies as Glybera and Luxturna) for the general population. The

public opinion on somatic cell genome engineering is not homogeneous also because there are known unwanted “off-target” side effects, such as triggered molecular events (point mutations, inversions, translocations, insertions, and deletions), echo effects in other locations elsewhere in the genome, and time-delayed events. Public opinion on germline cell genetic engineering is much more unified and unequivocally concerning, featuring moral, religious, social, societal, and human research considerations (Liao 2019). It has been stated that genetic engineering generates threats to our cells, ourselves, and our civilization (Baylis 2019). It threatens our cells by introducing the risk of unintended and unwanted modifications that may result in one or more of the three Ds – disease, disability, or death. It threatens ourselves by striving to use genome editing technology to improve on our biology, our social norms, and patterns of interactions, as demonstrated both by science fiction, as in the movie *GATTACA*, and the self-administration of CRISPR treatment by Josiah Zayner and Aaron Traywick and, possibly, other biohackers. It threatens our civilization by creating an illusion of perfectibility and the drive to eliminate disability and, by default, diversity (Comfort 2012).

Thus, there is a pressing need for a set of carefully conceived regulations for genetic engineering technologies for molecular medicine and other nonclinical crop and food industries, which should ultimately be approved by the public. Generating such regulations is not a trivial task, as they require consensus in public opinion, debates among experts, opinions from bioethical experts, involvement of biotechnologists, regulatory frameworks within legislatures, and final guidelines and oversight for the finally permitted limited application.

Summary

Rapid recent developments in science have resulted in enormous technological advances in genetic engineering, but formulated important ethical questions regarding how best to harness their power for the benefit of humankind. As in the

case of other technological advances, such as atomic energy, society should be ready to apply such advancements wisely and carefully. Premature applications of the possible can lead to the morally impossible. As a renowned geneticist Eric Lander stated, “. . . we have only just skimmed the three-billion-year-old genetic text and already they’re saying, ‘Hey! I think I can improve this!’” (2000). It is important to match the speed of discoveries in the field of genetic engineering with an appropriate depth of contemplation regarding its applicability in human life, for the individual and the collective.

Genius

Dean Keith Simonton
Department of Psychology, University of
California, Davis, CA, USA

Abstract

Although the Latin word *genius* first emerged in the mythology of ancient Rome, it eventually acquired three strictly secular meanings in the English language: (a) genius as a special talent that any person might have for a particular enterprise; (b) genius as eminent achievement in a culturally valued domain of creativity or leadership; and (c) genius as earning a superlative score on an intelligence test. Extensive empirical and theoretical research has been conducted using all three definitions. The resulting findings indicate that the three definitions correspond to largely separate phenomena. For example, having a special talent does not necessarily develop into highly acclaimed accomplishments, nor it is required that either of the former two guises of genius corresponds to an exceptional IQ. These three phenomena therefore bear distinct relationships with what have been identified as five aspects of the possible, namely, exploring possible worlds, exploring possible selves, exploring possible pasts, exploring possible futures, and exploring possible theories. After articulating some of the potential connections between genius and the possible, it becomes evident that there exists a rich potential for further research.

Genius · Creativity · Leadership · Talent · Combinatorial theory · Free will

Alternative Definitions of Genius

The concept of genius has a long history that produced a rich etymology of multiple meanings (Ball 2014; Murray 1989). The Latin word *genius* originated in ancient Roman mythology. In simple

terms, each individual was born with a “genius,” a tutelary deity who functioned like a guardian spirit over the course of that person’s life span. Subsequently, the word’s meaning expanded to encompass more secular usages. For example, genius later came to refer to a “Natural ability or capacity; quality of mind; the special endowments which fit a man for his peculiar work” (*American heritage electronic dictionary* 1992). Thus, one could have a genius for carpentry or landscaping. This particular meaning often rendered *genius* interchangeable with *talent*. This potential semantic overlap is apparent in Francis Galton’s (1865, 1869) studies of genetic inheritance, where he first used the word talent before switching to genius just 4 years later.

However, Galton (1869) also used a far more demanding definition that requires the achievement of eminence in a culturally valued domain. In particular, the status of genius required “the opinion of contemporaries, revised by posterity” that establish a given individual as “a leader of opinion, . . . an originator, . . . a man to whom the world deliberately acknowledges itself largely indebted” (p. 37). This concept of genius falls in line with another dictionary definition: “Native intellectual power of an exalted type, such as is attributed to those who are esteemed greatest in any department of art, speculation, or practice; instinctive and extraordinary capacity for imaginative creation, original thought, invention, or discovery” (*American heritage electronic dictionary* 1992). Two points about this latter definition are noteworthy. First, the notion of inborn talent is still retained, but now that talent has to be actualized in terms of genuine accomplishments, as assessed by the consensus of contemporaries and posterity. Second, genius can be manifested in a great diversity of achievement domains – virtually every domain of creativity and leadership. Indeed, this diversity is witnessed in the domains that Galton (1869) chose to investigate “hereditary genius,” domains like science, literature, music, and painting, as well as politics, warfare, jurisprudence, and religion (see also Cox 1926; Simonton 1988). That said, genius tends to be most strongly associated with creative domains (e.g., Kroeber 1944; Murray 2014). In particular,

the most notable and uncontested geniuses by the achieved eminence definition are usually visual artists, creative writers, philosophers, and scientists. Examples include Michelangelo, Shakespeare, Descartes, and Einstein.

One final definition is the most recent but also among the most commonplace: A genius is someone with an extremely high IQ score on a standardized intelligence test. For example, one standard dictionary asserts that a genius is “A person who has an exceptionally high intelligence quotient, typically above 140” (*American heritage electronic dictionary* 1992). Although the specific cutoff of IQ 140 may seem a bit arbitrary, it actually originates in Lewis M. Terman’s (1925–1959) classic longitudinal inquiry in which this criterion was selected because it represented the top 1% of the population on the Stanford-Binet Intelligence Scale. Because that scale was devised in 1916, the IQ definition is only a little more than a century old. It departs from the other definitions in yet another fashion. Where the previous conceptions of genius concerned what made a person unique, the IQ definition treats everybody according to their placement on what purports to be a single dimension, namely, general intelligence (Spearman 1927). To be sure, some investigators have argued that there are multiple intelligences (most notably Gardner 1983). Yet from a purely psychometric perspective, ample evidence indicates that various assessments of alternative intellectual faculties are sufficiently correlated that a single factor underlies them all (Nyborg 2003). Hence, the IQ definition remains primarily generic rather than specific. Scientific research has produced no standardized aptitude test that assesses a bona fide “poetry IQ,” a “chemistry IQ,” or anything else domain specific. Instead, domain-specific measures tend to assess “achievement,” or acquired expertise.

Consistent with this last observation, IQ scores bear only a modest correlation with achieved eminence in most domains (Simonton 2009). The association is not zero, but it is too small to consider IQ and achievement as representing alternative manifestations of the same genius definition. By the same token, those who are highly

gifted do not necessarily grow up to become eminent achievers, nor must they score at superlative levels on IQ tests (Winner 2014). Accordingly, it is possible to distinguish three major definitions of genius that may bear some relation with the possible: (a) genius as a special talent for some endeavor; (b) genius as achieved eminence in a significant domain; and (c) genius as stellar intelligence as assessed by an IQ test.

Research on the Various Guises of Genius

Corresponding to each of the three genius definitions is a large body of empirical and theoretical research (Albert 1992; Simonton 2014b). Some of the research findings may have relevance in understanding some aspect of the possible.

The first definition has an obvious linkage with inquiries into childhood giftedness and talent in a diversity of domains, such as sports, chess, music, and mathematics (Heller et al. 2000). All of these domains require the acquisition of a specialized expertise, yet those youths who display a “genius” for the domain exhibit two outstanding features (Simonton 2014a). First, they take less time acquiring the necessary domain-expertise and thus “get better faster.” Second, they perform at higher levels for a given amount of expertise and thus exhibit “more bang for the buck.” Both of these advantages presumably ensue from underlying genetic factors. Even so, teasing out the behavior genetics behind such talent is not easy because the phenomenon turns out far more complicated than assuming simple linear and additive relationships (Simonton 1999). Science is certainly far from the point of estimating a talent profile based on DNA testing. In fact, the genetics behind general intelligence – a far simpler task – has yet to be fully fathomed (Plomin and Spinath 2004).

Surprisingly, empirical research on genius as eminent achievement goes back almost two centuries (Simonton 2014c). The first such study was incorporated by Quetelet (1835–1968) into a much larger monograph that established the normal “bell-shaped” curve in the statistical

treatment of human behavior. Yet the first monograph exclusively devoted to eminent achievers was Galton (1869), who was mentioned earlier. He applied Quetelet's concept of the normal distribution to what he called "natural ability" and then proposed that those at the upper tail of this distribution would inevitably attain distinction as either creators or leaders. Galton also argued that natural ability was in fact *natural* in the sense that it was strongly inherited and thus passed down through family pedigrees. Of course, subsequent research shows that environmental factors, such as family background and education, also have a major role to play in the emergence of genius (Simonton 2014a). In addition, to attain distinction in well-established domains of achievement, a considerable amount of time must be devoted to the acquisition of domain-specific expertise (Ericsson et al. 2018). Genius is both born and made.

Turning to the third definition of genius, namely, genius as superlative IQ, the research is comparatively rare. That does not mean that investigators rarely use intelligence tests. On the contrary, those measures are among the most frequently used and best standardized instruments in psychology. The problem, rather, is that few inquiries even attempt to capture a single participant who scores at the genius level of, say, IQ 140. After all, if that threshold marks the top 1% of the general population, a researcher might need a sample of least 100 to have any chance of obtaining a single case. Consequently, investigators adopting this definition have to use a special methodology to obtain a reasonable sample size for empirical research. Terman's (1925–1959) longitudinal study mentioned earlier was able to obtain a sample of more than 1500 high IQ boys and girls, but he was only able to do so by canvassing entire California school systems, largely using teaching nominations to preselect the "best and the brightest" before anyone started taking actual tests. Likewise, when Hollingworth (1926, 1942) conducted her pioneering work on the intellectually gifted, including children with IQs exceeding 180, she relied on the huge student populations available in New York City. The difficulties magnify when a researcher wants to

assess psychometric IQ in adult populations. Most standardized instruments designed for adults do not finely discriminate those at the upper tail of the IQ distribution. For that reason, when Roe (1953) studied 64 eminent scientists, she asked the Educational Testing Service devise a special test that focused on that elite subgroup. Even then, the eminent physicists in her sample simply refused to take the mathematics portion of the test, finding it insultingly easy!

Genius and Alternative Manifestations of the Possible

In laying out the field of the possible as a possible field of inquiry, Glăveanu (2018) described the following five possibilities: exploring possible worlds, exploring possible selves, exploring possible pasts, exploring possible futures, and exploring possible theories. Theoretically, if there are three distinct genius definitions and five forms of the possible, there are 15 potential combinations. In practice, however, genius-possible combinations vary greatly in inherent interest for future research. So here just the best possibilities will be discussed.

The exploration of possible worlds has an obvious connection with genius as achieved eminence in a culturally valued domain. Indeed, it is hard to imagine instances where geniuses do not attain distinction by such explorations. Artistic creators, such as writers, painters, and composers, produce masterworks that frequently depict worlds that never before existed. Scientific creators make surprising empirical and theoretical discoveries that generate new possibilities regarding how the world works, such as the operation of DNA or the phenomenon of black holes. Outstanding leaders in politics, business, and religion will often offer their followers, whether citizens, consumers, or believers, alternatives to the present world via innovative policies, products, or precepts.

Needless to say, these possible worlds may more strictly represent either possible futures or possible pasts as well. The creators of science fiction most often illustrate the former by

projecting present humanity into some utopian or dystopian world. Climate scientists will create possible futures, but in their case, the forecasts are predicated on mathematical or computer models. Working in the reverse time direction, the authors of historical novels will conceive pasts that could not possibly have been known, such as hypothetical conversations or conjectural romances, and at times may impose counterfactuals that generate alternative histories. Creative scientists working in certain disciplines, such as archeology, paleontology, evolutionary biology, geology, and cosmology, will also hypothesize possible pasts and even apply counterfactual thinking. An instance of the latter is found among the cliometricians who tackled such questions as whether slavery in the United States was economically viable, thus rendering the Civil War necessary rather than superfluous for its destruction (Fogel and Engerman 1974).

Under the genius-as-eminence definition, all of the possible worlds, futures, and pasts conceived by the creators or leaders were of sufficient importance to earn the person an enduring spot in history – the judgment of posterity that confirms the assessment of contemporaries. Uncontroversial examples would have to include Isaac Newton's *Mathematical Principles*, Charles Darwin's *Origin of Species*, René Descartes's *Meditations on First Philosophy*, Leo Tolstoy's *War and Peace*, Dante Alighieri's *Divine Comedy*, Emily Dickinson's poems, Michelangelo Buonarroti's Sistine Chapel frescoes, Ludwig van Beethoven's Fifth Symphony, Abraham Lincoln's *Emancipation Proclamation*, James Watt's steam engine, and Martin Luther's *Ninety-Five Theses*. In truth, thousands more undoubtable instances can be offered, particularly when turning to non-Western civilizations for further illustrations (Kroeber 1944; Murray 2003).

Yet the idea of exploring possible selves does not require such grandiose standards. In fact, such exploration ties more closely with the genius as talent definition, in which each person is endowed with some special capacity for success in a vocation or occupation. Because individuals are not born with advanced knowledge of what this peculiar genius might entail, they have no other option but

to test various possibilities until they finally discover their "thing" or "passion." It might be teaching swimming or raising pigeons or making apple pies. In some cases, that specific talent may align with a domain of creativity or leadership in which the individual ventures into the realm of potential achieved eminence. But it does not have to go that far. Just discovering our true genius in everyday affairs suffices. Still, to get there, the exploration of possible selves is most often required.

At this point, it becomes appropriate to bring in the genius as high IQ definition. Why do some people find that they have a special talent in a culturally valued domain and yet fail to cultivate that talent to achieve eminence in that same domain? One critical factor may in fact entail the level of general intelligence. Not only does research show that such intelligence correlates positively with success in a great diversity of occupations and professions (Gottfredson 1997), but also that those who attain eminence in most domains of creativity and leadership can claim high IQs (Simonton 2009). Hence, general intelligence, as approximately assessed by IQ tests, may determine what it takes to make it over the top – to convert personal talent to sociocultural genius. In this view, specific talents must combine with generic intellect that is then channeled into the particular domain of choice.

Now that all three genius definitions have been incorporated into the discussion in one way or another, the only item left to consider is the fifth potential possible, to wit, exploring possible theories. Here the most promising theoretical system may be the combinatorial theory of exceptional creativity developed by Dean Simonton (2003, 2010). Through an integration of mathematical models, computer simulations, and empirical tests on samples of actual creative geniuses, this theory proposes not only that creativity requires the combination of ideas or behaviors, but also that these new combinations must be generated with little or no prior knowledge of their usefulness or utility. Accordingly, the novel combinations must be subjected to subsequent evaluations to see whether they truly work, thus separating the bona fide actual from the merely possible. Although the development of this theory is recent,

it can be said to formally implement concepts that have been around for many decades, including trial and error (Bain 1855–1977), generate and test (Newell and Simon 1972), selection by consequences (Skinner 1981; see also Epstein 1991), and blind-variation and selective-retention (Campbell 1960; Simonton 2011). In any case, various combinatorial processes and procedures enable the creative genius to function as a genuine causal agent in history, producing potential futures that might not otherwise exist, nor even anticipated (Simonton 2018). As the philosopher Arthur Schopenhauer expressed it, “Talent hits a target no one else can hit; Genius hits a target no one else can see.”

Even if the above combinatory theory was originally designed to provide explanations and predictions with respect to creative genius, the same theory applies to everyday creativity, albeit the relevant processes and procedures operate at a more mundane level (e.g., less original combinations where the utilities are partially known, such as off-the-cuff spice additions to a favorite recipe). This more modest version of the theory then provides the basis for “free will,” or volitional choice, where the combinations are again selected based on a decision-making process that maximizes personal utility (Simonton 2013). In short, the combinatorial theory of creativity can also apply to the exploration of possible selves.

Conclusion

Given three separate definitions of genius and the five manifestations of the possible, the foregoing section may not have exhausted all of the potential pairings. Yet it should suffice to indicate some of the more prominent connections as well as underline their importance. That importance is both personal and sociocultural – ranging from possible selves to possible worlds.

Giftedness

Sally M. Reis and Joseph S. Renzulli
Neag School of Education, University of
Connecticut, Storrs, CT, USA

Abstract

Those labeled intellectually gifted either as children and/or adults exist in every ethnic, socioeconomic group and culture. Gifted and talented individuals exhibit a diverse and unlimited range of advanced learning and cognitive characteristics. They also differ, however, in cognitive, personal, and affective areas including academic traits, effort, temperament, educational achievement and attainment, productivity, creativity, and risk taking. Some individuals identified as gifted have very advanced capabilities and can self-regulate and sustain the effort needed to achieve personally, academically, and in their careers. Despite their label of giftedness, however, a significant number of very intelligent individuals fail to realize a high level of accomplishment or, as Glăveanu

(Eur J Psychol 14(3):519–530, 2018) suggests, realize their possible selves. This failure of realization either in their education or chosen professions often results in the label of underachiever in school or unfortunately, in life accomplishments. The reasons for their underachievement vary, but it is clear that some highly able and talented students are either unwilling or unable to devote the time and focus necessary to develop and realize their talents. The development of giftedness requires individuals to expend extraordinary levels of effort and focus, and some very high potential individuals do not or cannot make that commitment. This entry begins with definitions of giftedness and a brief overview of its history, before summarizing recent research in this area, and ending with research-based suggestions on how to develop giftedness and the educational and personal conditions to foster and enhance it.

Keywords

Intellectual giftedness · Cognitive ability · Academic talent · Creativity · Motivation · Task commitment · Talent development

Introduction

Despite the diversity of opinions in education and psychology regarding definitions of intellectual giftedness, several common themes emerge about intellectual giftedness and the academic and work conditions necessary for its development. The broad body of research related to intellectual giftedness is summarized in this entry, with a focus on highlighting seminal research on giftedness, and an overview of interesting and important theories to date. New research-based trends exist in defining, identifying, and developing academic gifts and talents, and scholars and researchers continue to debate definitions of giftedness. They also debate how intellectual giftedness develops and the specific characteristics of diverse groups of high potential youth. Understanding these characteristics helps educators and psychologists identify and nurture intellectual

gifts and talents in diverse populations of students. This entry also connects well to the possible as a field of inquiry (Glăveanu 2018), as educators who work with talented youth need to help them consider opportunities to imagine different selves in the future and how those selves connect with their vision of their talents over their lifespan.

Giftedness is an open, dynamic, multidimensional concept that is capable of building increasingly complex behaviors through self-organization and self-direction (Dai 2010; Dai and Renzulli 2008; Renzulli 2005, 2012). Theories about giftedness include the many ways in which intellectual giftedness develops; how culture defines and influences giftedness, and the presence and importance of nonintellectual components of giftedness in determining performance. Other themes relate to the assessment of intellectual giftedness which, Sternberg (2005) believes, is too often validated against the socially approved criteria resulting in the appearance of validity that may not exist within a specific sociocultural group. It is critically important to understand that there is no right or wrong definition to intellectual giftedness, especially in very high achieving children. Some theorists believe that we can identify gifted individuals across domains, even in children at a young age, as if there is a golden chromosome that enables one to be identified with the right assessment tools. Others believe that giftedness occurs within a domain, such as those who are scientifically or mathematically or even artistically gifted. Different conceptions of giftedness across cultures (Phillipson and McCann 2007) suggest the need for research and understandings of the ways in which languages and cultures influence and contribute to giftedness. And some theorists argue that a distinction exists between academic or lesson-learning giftedness and creative/productive giftedness (Renzulli and Reis 1985; Renzulli 2005).

Over three decades ago, Renzulli first summarized research suggesting that creative productive giftedness includes the interaction of above average ability, task commitment, and creativity that exists in certain people, at certain times, and under certain circumstances (Renzulli 1978, 1986,

2005). For example, Rachel Carson demonstrated her abilities, task commitment, and creativity in her groundbreaking work in both biological sciences and writing, leading to the creation of a book that created a new field and had influence on every aspect of ecology and protecting the environment from pesticides. This notion of giftedness argues against considering giftedness as a trait such as eye color or something that a child has or does not possess and therefore should be viewed from a more developmental perspective. For example, Gagné's (2000) Differentiated Model of Giftedness and Talent (DMGT) is another developmental theory that distinguishes giftedness from talent and discusses how outstanding natural abilities (gifts) can develop into specific expert skills (talents). Gagné believes that those labeled as gifted have the potential for extraordinary work and that those who are subsequently identified as talented develop their inherent potential for contributions. He identifies components that interact in multiple ways to foster the transition of moving from having natural abilities (giftedness) to systematically developed skills (talents).

Many of the chapter authors in two seminal books on conceptions of giftedness edited by Sternberg and Davidson (1986, 2005) identify similar themes about the developmental nature of intellectual giftedness, as do Dai (2010), Subotnik et al. (2011, 2012). One of the leading scholars in the area of intelligence, Simonton (2005, 2008), for example, proposed a model of giftedness in which talents result from the coming together of genetic components that develop on individual domain-specific trajectories.

Few, if any, researchers or theorists who have studied intelligence or intellectual giftedness continue to believe that giftedness is unidimensional rather than multidimensional. Similar to psychologists who believe in the multidimensional aspects of intelligence (Carroll 1993; Gustafsson and Undheim 1996), theorists who study intellectual giftedness (Gagné 2000; Gardner 1983, 2016a; Renzulli 1986, 2005; Sternberg 1985, 2005) agree that we must look beyond the traditional early notions stating that intellectual giftedness can be equated with a high score on one

assessment such as an IQ test. In fact, current research on assessment has found that large, significant discrepancies among verbal, figural, and quantitative reasoning abilities as measured by standardized IQ tests are more common among high- and low-ability students than among average-ability students (Lohman et al. 2008). This research argues against using a single composite IQ score for identification for gifted programs, as it may cause us to miss many highly able students whose scores are brought down by a single area of relative weakness, particularly students from high poverty or multicultural backgrounds. And of course, we know that potential gifts and talents remain latent in many people that are not favored with optimum circumstances and the opportunities, resources, and encouragement to develop their special talents (Renzulli and Reis 2014).

A strong body of research supports a broader based conception of giftedness as a combination of multiple qualities, in addition to intellectual potential, which includes nonintellectual traits such as motivation and creativity (Renzulli 1978, 2005; Sternberg 2005) and positive beliefs in self (Reis 2005). In this research, for example, Reis studied eminent, gifted women such as Mary Hunter Wolf, the first woman Broadway producer. This research included case studies of American women pioneers who, in addition to their intellectual talents, persevered despite negative stereotyping and other obstacles, to actively develop their talents and complete creative and important work.

Those labeled intellectually gifted are a varied group with differing cognitive profiles, learning disabilities, attention deficits, and varied learning styles. Some struggle with procrastination and perfectionism, and faster or slower processing speeds. Some high ability individuals demonstrate asynchronous (uneven) development, cognitive and/or academic relative strengths and weaknesses, or learning disabilities. The mere idea of intellectual giftedness itself has different meanings for different people, and discussions about these meanings are influenced by the culture, environment, and context in which gifts emerge, and the values associated with each. Not surprisingly, within different cultures, contexts, and environments, the outcomes of intellectual

giftedness vary. Cultural influences have been found to negatively or positively affect the choices and products that emanate from one's gifts, and one's ability to select, shape, and/or adapt one's environment (Sternberg 2018).

Biases and stereotypes about gender also have an impact on giftedness, as gifted males in many, if not most, cultures far surpass gifted women in accomplishment and professional attainments (Reis 1998, 2005). Reis proposed a theory of talent development in women that includes abilities (intelligence and special talents), personality traits, environmental factors, and personal perceptions, such as the social importance of the use of one's talents to make a positive difference in the world. In multicultural societies, it is usually the views held by the dominant culture about gender that generally guide the ways that giftedness is defined, identified and developed, with targeted opportunities, resources, and encouragement.

In addition to cognitive contributors to the development of high performance, a number of other factors referred to by Renzulli (2002) as "intelligences outside the normal curve" have also been found to play a role in the accomplishments of intellectually gifted young people and adults. Factors such as creativity, motivation, courage, optimism, sense of power to change things, empathy, and physical and mental energy are aspects of the gifts that we respect in the work of people such as Rachel Carson, Nelson Mandela, Mother Teresa, and Martin Luther King, Jr. (Renzulli 2002).

Important American Contributions to Research on Intellectual Giftedness

Seminal theoretical contributions related to research on intellectual giftedness are summarized in this section, which includes the historically important work of Terman, (Terman 1925–1959), and the recent works of Renzulli, Gardner, and Sternberg. The history of giftedness begins in America with Lewis M. Terman's edited five-volume series entitled *Genetic Studies of Genius* published between 1925 and 1959, resulting in a body of work that is widely acknowledged to be a

seminal contribution to the field of intellectual giftedness. The background of the use of the word "genius" in the title stems from his publication in 1916 of the Stanford-Binet Intelligence Scale, based on the work of Alfred Binet. Terman and his colleagues, using a revised test, identified gifted students, nominated by their teachers, who demonstrated what Renzulli has called "schoolhouse giftedness" as they performed well academically in the classroom.

The problematic legacy of Terman's work is his conjecture that an IQ score is synonymous with giftedness and that the highest IQ is equal to genius. This legacy has not been helpful to the field of gifted education and those researchers, psychologists, and educators who believe that giftedness is developmental and includes additional necessary noncognitive attributes such as creativity, motivation, focus, and executive function skills.

Three-Ring Conception of Giftedness. For many years following the publications of Terman's work, both psychologists and educators equated intellectual giftedness with having high scores on an intelligence or IQ test. Renzulli's (1978, 2005) definition (popularly known as the three-ring conception of giftedness) helped to shift the focus of previous discussions from an examination of gifted individuals to an examination of gifted behaviors and his landmark work hypothesized the inclusion of nonintellectual components in giftedness. He defined giftedness as reflecting an interaction among three basic clusters of human traits – above-average ability, high levels of task commitment, and high levels of creativity – stating that individuals capable of developing gifted behavior are those possessing or capable of developing this composite set of traits and applying them to any potentially valuable area of human performance. He also distinguished between schoolhouse or high academic giftedness and creative productive giftedness, arguing that many individuals who excel in school and are labeled gifted do not make creative contributions as adults because they lack both creativity and task commitment for creative productive giftedness (Renzulli 1986). His definition is widely used and adapted by some states and school districts across the country.

Renzulli (2005) included creativity as one of the three clusters, calling it co-cognitive, as opposed to a noncognitive cluster. Creativity is one of the clusters of abilities that is necessary for creative productive giftedness to develop in Renzulli's definition. This type of giftedness involves the development of innovative ideas or products that will be valued by general or targeted audiences. Creative-productive giftedness also requires above-average ability in one or more areas of human performance, sensible risk-taking, a sense of purpose, and the motivation to work hard for a prolonged period of time. In later work, Renzulli (2002) continued his work on the three-ring conception by examining personality and environmental factors that contribute to socially constructive behaviors reflected in the works of people who have made contributions to the greater good in all walks of life. These interactive factors are depicted by the houndstooth background of his three-ring conception (see Fig. 1).

Multiple Intelligence and Gifted Contributors and Goodwork. Gardner's (1983) theory of multiple intelligences (MI) proposes seven relatively autonomous but interactive intelligences, based on his work with individuals exhibiting

extreme cognitive abilities (or deficits) in particular areas, such as music or math, but not general cognitive superiority. The seven intelligences initially proposed by Gardner were linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, interpersonal, and intrapersonal. How does Gardner define intellectual giftedness? Gardner (1993) applied his MI theory to an analysis of the intelligences of creative leaders of the twentieth century, explaining that outstanding performance emanated from a particular rather than general intelligence. Gardner, for example, believed that Mahatma Gandhi excelled in intrapersonal intelligence and Einstein in logical-mathematical intelligence. Although these individuals excelled in one particular intelligence, Gardner theorized that most individuals exhibit some balance across levels of the various intelligences (Gardner 1993, 1995, 2016a). The GoodWork Project (Gardner 2016b) continues Gardner's long-standing efforts to probe the nature of good work across different professional domains and promote good work, described as high quality, socially responsible, and meaningful for making the world a better place. Gardner focuses on how people in diverse professions

Giftedness, Fig. 1 The three-ring conception of giftedness

can do good work, using examples such as Anita Roddick, the founder of the cosmetic company, The Body Shop, whose primary goal was to create a sense of humaneness in the business world. Roddick and colleagues undertook humanitarian work all over the world from living with poor families in Appalachia, West Virginia to working in refugee camps in Albania. Even after her death, with Roddick as their inspiration, the Body Shop continues to focus on social and environmental change.

Triarchic Theory, Balance Theory of Wisdom, and Successful Intelligence. Robert Sternberg developed his own multidimensional conception of intelligence, the triarchic theory of intelligence (Sternberg 1985) that has been universally debated and discussed. According to this theory, intelligence is the interplay between analytical, creative, and practical abilities in a given sociocultural environment. Analytical abilities are those most traditionally associated with intelligence and involve evaluating and analyzing information. Creative and practical abilities differ from traditional conceptions of intelligence as they are more associated with generating new ideas and applying knowledge in a given context. Sternberg's (1996) theory of successful intelligence explained how individuals can optimize their different strengths while compensating for their relative weaknesses. Successful intelligence shifts away from ability or aptitude measurement and relies on individualized assessments of achievement.

Sternberg is one of the few cognitive psychologists who has conducted research on the ways his theories of intelligence apply to giftedness (Sternberg 2005). Gifted individuals, according to Sternberg, demonstrate three common attributes that comprise his definition of intelligence (Sternberg 1985, 1996), including analytical giftedness, demonstrated by an ability to analyze and evaluate one's own ideas and those of others; creative giftedness, an ability to generate one or more major ideas that are novel and of high quality; and practical giftedness, an ability to convince people of the value and practicality of ideas. According to Sternberg, gifted individuals capitalize on their strengths and compensate for or correct their weaknesses. (Sternberg 1996).

People may show different patterns of skills, in general, and of giftedness, in particular periods over the course of their lives.

Summary of Giftedness and Talent Development for the Future

Research on the development of intellectual giftedness has demonstrated that talents develop across multiple domains and over time, with the right combination of innate talent, parental support, expert teaching, and the desire of the individual to apply the effort necessary to develop innate talents (Bloom 1985; Csikszentmihalyi et al. 1993; Renzulli 1978, 2012). Some research, such as Bloom's classic work, examined the childhoods and backgrounds of highly accomplished individuals across domains to identify common features contributing to their talent development. High levels of talent development require constant attention, nurturing, and focused effort and task commitment. Research also suggests that supportive experiences at school, in the community, and at home are critically important forces in transforming potential into fully developed talents (Bloom 1985; Csikszentmihalyi et al. 1993).

Subotnik et al. (2011, 2012) recently developed a new definition of giftedness as well as a comprehensive organizational scheme that integrates giftedness, talent, expertise, and eminence, conceptualizing them as a sequence of stages that under the best of circumstances lead to eminence. They acknowledge that the abilities of individuals do matter, particularly their abilities in specific talent domains that have different developmental trajectories. The variation in domains includes aspects such as when they start, peak, and end, and by the opportunities provided by society that are crucial at every point in the talent development process. In this theory, the authors highlight their belief that society must strive to promote these opportunities, but that individuals with talent must also assume responsibility for their own growth and development.

Renzulli and Reis (2014) have continuously advocated that schools need to become places for talent development and that educators should help all students develop their talents by providing

them with opportunities, resources, and encouragement to do so. In particular, this is critically important for students of poverty and for those who have less opportunities and resources to develop their talents. They advocate that some enrichment opportunities should be provided for all students to enable teachers and other observers of the work of young people better understand which students should receive additional and advance opportunities to develop their gifts and talents. Across these scholars, a clear trend exists in perceptions that giftedness can be developed – that there is a need for talent development both in schools and home environments. One important goal of developing students' high potential and aptitude is the need to actively develop outstanding achievement, creativity, or eminence in adult life, resulting in a higher number of creative and intellectual work produced in all fields. Research is increasing but we know little about the outcomes and effects of underachievement in talented adults and the feelings of failure and/or anxiety or depression that adults experience when they fail to realize their high potential. And although the area of giftedness across the lifespan is discussed in many different publications in our field, few comprehensive studies have been conducted on how talents and gifts emerge in adults and the types of support is necessary to develop these gifts and talents. Much important work remains to be accomplished.

Goal Orientations

Maciej Karwowski¹ and Ross Anderson²

¹University of Wrocław, Wrocław, Poland

²University of Oregon, Eugene, OR, USA

Abstract

This entry discusses the interplay between motivational goal orientations, creativity, and the possible as a field of inquiry. Crucial theoretical categories of goal orientations: mastery-versus-performance and approach-versus-avoidance, as well as the integrated 2×2 goal orientation model are discussed altogether with empirical results showing their links with creativity. Drawing on classic theories of achievement goals, this entry also discusses two widely studied constructs that are specifically relevant for goal orientations, creative mindsets, and creative confidence, all contextualized within the possible.

Keywords

Mastery and performance goals · Approach and avoidance · Fixed and growth mindsets · Creative self-efficacy

Creativity is goal-directed activity. Although simple, this statement covers an essential characteristic of creative activity. Even if popular literature promotes many examples of famous creators who benefited from “aha moments” – sudden insights (Insight) that seemed to come out of nothing – the idea that activity leading to creative accomplishment is unintentional is extremely unlikely. Quite the opposite is true. Creative activity requires a confluence of different characteristics and opportunities, including: cognitive (divergent thinking, intelligence), personality-related (openness, curiosity), motivational (creative self-efficacy, intrinsic motivation), environmental (supportive climate), time devoted to training, and, of course, luck. Creative activity most often begins with a goal, even if exploratory, and goals play a crucial role in motivation and self-regulation during creative activity. How individuals frame their goals

plays an overarching role in shaping the possible for personal development and outcomes in one's life and work. In this way, the clearest link between goal orientations and the possible exists at the level of exploring possible selves (Glăveanu 2018).

Importantly, being goal-directed does not mean that all creators always have a clear perspective of an end-product to be achieved. Goals might be operationalized in more general and less material terms than a published book, finished piece of art, or composed symphony. For instance, the development of competency and eventual mastery with a technique, material, or process will open different possibilities than goals of public recognition. This entry discusses how the conceptual framework of achievement goals, influential in motivational literature, can inform creativity research and, in turn, connect to the possible as a field of inquiry. To this end, the history of achievement goals and the evolution of this construct is briefly discussed alongside the scarce empirical evidence that links achievement goals to creativity. Next, more distal components of achievement goals theories – creative mindsets and creative self-efficacy – are introduced. This entry closes by showing some promising research areas allowing for effective integration of goal orientation models with creativity and the possible.

The interests in achievement goals date back to the mid-1970s when two psychologists independently proposed the initial framework of analyzing and studying purposes that might motivate (or de-motivate) people during their activity. Carol Dweck (1975), continuing her work on learned helplessness, developed the mastery-versus-performance goals distinction. John Nicholls (1976), continuing his research on self-perception of abilities and competence, developed a theory of ego-versus-task involvement goals. Although coming from different theoretical traditions and varying in terms of specific propositions, these two models share crucial assumptions. Given that the mastery-approach perspective is more prevalent in the contemporary literature, this approach to achievement goal distinction is followed in this entry.

Mastery and Performance Goals

In Dweck's works, mastery orientation was initially theorized as a characteristic of children who failed under challenging tasks and, yet, still displayed an adaptive pattern of attribution, making their failure productive. In this way, Dweck, and researchers that followed, found that people with mastery orientation attribute their struggles and failures to either insufficient effort (i.e., *I did not try sufficiently hard*) or ineffective strategies (i.e., *I dealt with this problem the wrong way*). Therefore, mastery orientation, sometimes called *learning goals*, posits the main reason for engaging in a particular activity is developing an individual's competence and mastering a task. When faced with a failure, people with a mastery orientation are able to persist and continue working on a problem. Mastery orientations make failure an expected, productive struggle on the path toward achievement. In line with Heidegger's (1962) ideas about the possibility of becoming, the openness to unexpected setbacks in a mastery orientation fuels a latent potential for growth rather than a deficit orientation toward one's limits.

Performance orientation was theorized as the result of maladaptive patterns in the face of challenge and failure. People holding performance goals orientation explain their failures as a lack of sufficient ability to succeed in a task and often react with negative, self-defeating emotions. The purpose of performance goals can be twofold: (a) to *show off* and demonstrate competence in a particular task or (b) to *hide* and avoid showing incompetence when faced with a challenging problem. The performance goals orientation was theorized to affect individuals maladaptively by evoking misdirected attribution and negative emotions, leading to suboptimal effects on motivation and achievement. Narrowly focused performance-directed goals, essentially, close off individuals from different possible outcomes.

Although several theorists predict that mastery orientation will lead to positive effects while performance orientation is detrimental leading to adverse outcomes, for example, in school, the evidence for such claims is scarce. Several studies demonstrated that mastery orientation is indeed

connected with positive emotional reactions and generalized positive affect, and performance orientation correlates with negative affective states and anxiety. What is far less clear, though, is the role of these orientations for different types of effective functioning under different circumstances – be it learning, problem-solving, or the “what-if” possibility thinking, key to creativity.

Gaps in the literature prompt the question – what is the role of goal orientation in the creative process toward the possible? Given that creativity is polimotivational, where conflicting motives can lead to creative activity (Anderson and Karwowski 2020), there are convincing reasons to argue that under certain circumstances, both mastery and performance orientations may be conducive. On the other hand, there is a classic theorizing and research tradition in creativity literature that demonstrates the benefits of intrinsic motivation for creative thought and action (Amabile 1996). Mastery orientation is conceptually close to intrinsic motivation: both are driven by curiosity, personal value of a task, and need for cognition. Still, while intrinsic motivation denotes activity driven by its autotelic value, mastery orientation is, by definition, *telic* – goal-oriented to develop one’s skills and master a task. This reasoning would lead to a prediction that mastery orientation, thanks to its focus on development, improvement, and learning, will support creative thinking and activity and what they make possible for oneself and the world around them. Performance orientation, with its emphasis on competition, demonstrating one’s competence, and avoiding overly difficult situations that might demonstrate limitation, seems like an antithesis of creativity and the possible. But what is the empirical evidence for this prediction?

Intriguingly, the literature on the links between mastery-versus-performance goal orientation and creative potential and accomplishment is sparse. In a study of Chinese R&D employees (He et al. 2016), mastery orientation was found to be significantly and positively, yet, at the same time, weakly ($r = 0.18$), related to creativity, while performance orientation was negatively linked to creativity. Apart from simple correlational evidence, empirical relationships were more

complicated. Mastery orientation moderated the relationship between failure feedback and creativity in the work environment. The link between supervisors’ failure feedback and employees’ creativity was positive and significant among employees high in mastery goals, only. This moderation implies that goal orientations might not necessarily serve as direct predictors of creativity, rather goal orientations might be interdependent with other factors and, in a way, determine what a person makes possible from constructive feedback.

That logic is consistent with the results of an experimental study that explored the links between risk-taking and creativity and the potential moderating role of goal orientations (Simmons and Ren 2009). Results demonstrated that, not only were people more creative under a risk-taking condition, but also when risk-taking was accompanied by a more adaptive mastery goal orientation. Taking risks can be seen as a disruptive necessity to new possible futures for oneself and the surrounding sociocultural environment. In educational settings, Beghetto (2006) has shown that mastery orientation significantly predicted students’ creative self-efficacy, but – contrary to what might have been expected – he also found positive links between performance goal orientation and creative self-efficacy. A recent longitudinal study (Jankowska and Karwowski 2019) focusing on the development of children’s creative thinking found that parents’ performance orientation was positively related to children’s initial level of creative ability but negatively predicted the developmental changes in their children’s creative abilities. In other words, although children whose parents held stronger performance goals started with higher creative abilities, their developmental trajectories not only were flatter but even tended to decline with time. Parental goal orientations can limit what is possible for their children (Lebuda et al. 2020). In contrast to the potential negative influence of parental performance goals orientation, parents’ mastery orientation was unrelated to changes in children’s creative thinking. A study on teachers (Hong et al. 2009) demonstrated strong positive links between their own mastery orientation and the creative skills used by

their students. They found no relationship between teachers' performance goals orientation and students' creativity.

In sum, these results allow for a tentative conclusion that while mastery orientation, in an individual, their parent, or their teacher, may be conducive to creativity, the evidence regarding performance orientation is mixed. Importantly, the potential role of mastery orientations should not be overestimated, given the consistently weak observed effect size. There are studies demonstrating effects of performance goals on creativity as negative, null, or positive; as such, an unambiguous conclusion regarding its role is impossible, at this time. These ambiguities call for new studies on different samples with well-established measures and a more finely ground model of goal orientations relevant to creativity and the possible, specifically. Such a model, extending the pure mastery versus performance dimension, has been proposed in the achievement goals literature by synthesizing it with a classic approach-versus-avoidance perspective.

Approach and Avoidance Orientation

Early works on mastery and performance goals orientations ignored the possibility that these two goals may be approach- or avoidance-driven. This is surprising, as the distinction between approach and avoidance is classic in motivational literature (see discussion in Elliot 1999). While approach orientation denotes expecting the possibility of positive outcomes and striving for success, avoidance orientation is linked with failure expectations and, consequently, avoidance of potentially tricky tasks. The combination of mastery-performance goals with approach-avoidance goals was proposed by Elliot (1999), who demonstrated that a simultaneous analysis provides an additional input into motivational goals. Elliot suggested that performance goals are not always detrimental for adaptive functioning and achievement, and should be divided into approach versus avoidance orientations. Performance-approach goals hold a focus on the attainment of sense of competence, and performance-avoidance hold a focus on

avoidance of sense of incompetence. In early conceptualization, mastery goals were theorized as approach goals only, with an emphasis on the development of competence and task mastery; yet, a 2×2 achievement goals framework (Elliot 1999) delineated a mastery-avoidance category (e.g., avoiding self- or task-referential incompetence).

Though performance-avoidance goals may be detrimental, the central premise of the 2×2 achievement goal model is that performance-approach goals, with a focus on normative competence, might be conducive to achievement as well. Thus, the introduction of the approach-avoidance continuum into research on achievement motivation has allowed for more nuanced interpretations of motivational goals' effects. But how does this distinction inform discussion about creativity and the possible that it opens and expands for self and others?

A safe conclusion from two decades of studies is that creativity benefits from approach orientation and is suppressed by avoidance orientation. This seems commonsensical – feeling agentic to be creative requires activity that is often risky and unknown, so exploration typical for approach motivation is necessary for creativity. It is much harder to imagine or theorize how avoidance motivation could be useful for creativity. Empirical evidence confirms that approach motivation helps to solve insight problems and generating ideas (Friedman and Förster 2002), and approach-related emotions, both positive (e.g., feeling happy) and negative (e.g., feeling angry), are far more conducive to creativity than avoidance-related emotions (both positive, e.g., feeling calm and negative, e.g., feeling sad; Baas et al. 2008). However, as Roskes and her colleagues (Roskes et al. 2014) theorized, avoidance motivation may boost creativity under certain conditions, like the presence of constraints that channel cognitive resources. Providing an individual solving a problem with specific, procedural instructions illustrates how a channelling, yet constrained situation could help solve creative problems for people who are driven by avoidance motivation (see Roskes et al. 2014).

Considering the 2×2 achievement goals model again, a natural prediction would be that mastery-approach goals and, to a lesser extent, performance-approach goals should be conducive to creativity, while the link between creativity and avoidance-related goals – both: mastery-avoidance and performance-avoidance is less clear. A study on Taiwanese junior high school students (Peng et al. 2013) partially confirms this prediction. While both approach goals (mastery and performance), as well as mastery-avoidance goals, indirectly boosted students' divergent thinking as a result of their autonomous motivation, performance-avoidance goals were unrelated to divergent thinking.

Although the 2×2 achievement goals model forms a useful motivational framework for creativity literature, more research is needed to fully untangle the role of, and conditions for, mastery-performance and approach-avoidance dimensions for creative thinking, activity, and achievement. Research suggests these goal orientations are not always contradictory in adolescence, but may actually coexist. As such, future studies may benefit from not only showing static correlational links between goal orientations and aspects of creativity but also by analyzing the interrelations and interactions of goal orientation to explain creative functioning. Additionally, future research should investigate the potentially varying role of goals for different phases of the creative process. Future studies might also benefit from including relevant antecedents and consequences of goal orientations into a testable theoretical model. Two existing constructs – creative mindsets and creative confidence – hold unique promise for such models. The remaining part of this entry will focus on the role of these factors in relation to goal orientations and the possible.

The Role of Creative Mindsets for Goal Orientations

Creative mindsets refer to a specific part of implicit theories that people carry about creativity, specifically, the perceived roots of creative potential and perceived susceptibility for creative

potential to change or remain stable. The idea of mindsets was introduced by Dweck (e.g., Dweck 1986), who proposed that people differ in their beliefs about the potential changeability of human characteristics and the sources for that change. So-called entity theorists (people holding a “fixed” mindset) believe that traits, such as intelligence, are inborn and impossible to change – clearly at odds with holding a philosophy of the possible for oneself and others. Incremental theorists (people holding “growth” mindset) perceive human characteristics and abilities as malleable with potential for change and development given sufficient effort, training, and use of effective strategies – an orientation toward the possible.

In creativity literature, there is a growing interest in creative mindsets as plausible regulatory mechanisms explaining the likelihood of engaging in creative activity (Karwowski 2014). Interestingly, in the case of creativity, fixed and growth mindsets do not form the opposite ends of one continuum but often coexist (Karwowski et al. 2019b). Holding these seemingly contradictory beliefs simultaneously could relate to common societal narratives about an assumed destiny for creative genius, individual experience of success in one domain and not another, or other unexamined theories individuals carry. Indeed, especially among people who value creativity and have prior creative achievement, the paradoxical high-growth-high-fixed pattern is surprisingly often met.

Regarding creativity and the possible, it is important to ask why mindsets matter for goal orientations? In her early theory, Dweck proposed that mindsets are among the most critical factors that cause goal orientations – people who hold a fixed mindset do not believe in the possibility to change and improve and naturally adopt a performance goals orientation that. Consequently, those holding a fixed mindset engage in activity for the sake of confirming their self-perception. For instance, they may aim to demonstrate to others that they are able to solve a specific problem or that they are better than others in a particular task. At the same time, such people tend to avoid a difficult task that may form a threat for their self-perception in case they fail. Incremental

theorists – people holding a growth mindset – are much more likely to adopt mastery goal orientation with a focus on improving in a task and developing their skills.

Although studies conducted in educational settings confirm Dweck's propositions, the question about the links between creative mindsets and goal orientations in creativity is still to be explored and could support theorizing around motivation and orientations toward the possible. A tentative answer, consistent with hypotheses, was established by a study from Mexico (Puentes-Díaz and Cavazos-Arroyo 2017), showing that, indeed, growth mindset positively predicted mastery orientation, while fixed mindset positively predicted performance-avoidance goals.

Given increasing interest in creative mindsets, it seems prudent to advise future researchers to include goal orientations into their theoretical framework, research designs, and studies. One might consider performance goals as mediators in the relationship between mindsets and creative behavior. Studying mindsets alone may, in part, explain the underlying belief but it does not test important mechanisms that lead from a belief to creative action. Not only are motivational goals among highly plausible mechanisms but their inclusion may also (even if partially) explain inconsistent findings reported in the literature. Indeed, it happens that some observed links between mindsets and creative thinking or efficiency of problem-solving are weak or even null (e.g., Hass et al. 2019). It seems likely that these mixed findings would be more understandable if goal orientations are taken into account.

The Role of Creative Confidence

Creative confidence is another key construct that should be emphasized when goal orientations are theorized in creativity research. Creative confidence may be operationalized as a more stable creative self-concept – “holistic cognitive and affective judgments of creative ability in and across particular domains” (Karwowski et al. 2019a, p. 399). Creative confidence also relates to more task- or situation-dependent creative self-

efficacy, or the “perceived confidence to creatively perform a given task, in a specific context, at a particular level” (Karwowski et al. 2019a, p. 399). Both aspects of creative confidence – creative self-concept and creative self-efficacy – are among intensively studied constructs in creativity literature, precisely because of their motivational functions.

Why does creative confidence matter in relation to goal orientations? Early theorizing posited that, while mastery orientation is usually conducive to achievement, performance orientation is especially harmful when accompanied by low perceptions of self-competence (Dweck 1986). In other words, one could expect that the links between performance goals and creativity are negative only among people who do not believe that they can be creative. In contrast, when creative confidence is high, it may buffer the negative effects of performance orientation. If followed consistently, this logic leads to a more complex model in which creative mindsets are antecedents of goal orientations with growth creative mindset building mastery orientation and fixed mindset translating into performance orientation. Those resulting goal orientations would strengthen or limit the chances for creative outcomes – mastery orientation would be expected to support creative thinking. However, the hypothesized negative role of performance orientation – specifically, performance-avoidance orientation – would be moderated by creative confidence. In that model, even if someone held a fixed creative mindset, believing in little potential for malleability of their creative skills and the skills of others, they would likely also hold a performance goal orientation and, yet, could still be expected to reach creative achievement if their creative confidence was high. In the context of the possible, creative outcomes that result from this mindset-to-mastery process can be considered the actualization of a possible self that also opens up new possibilities for others.

Although interesting, this hypothesized model awaits empirical examination. Previous studies focused on links between mindsets and confidence, showing that indeed people with a higher growth mindset tend to have higher creative

confidence than those with a fixed mindset (Karwowski 2014). Other research treated creative confidence as a mediator between mindsets and creative problem-solving (Royston and Reiter-Palmon 2019). The potential moderating effects of confidence in the link between goal orientations and creativity is yet to be tested.

Discussion

Goal orientations are essential for achievement motivation theorists and educational psychologists. Though often overlooked, their role for creative thought and action has implications for what is made possible for self and others. The overview presented in this entry emphasizes the potential fruitfulness of goal orientations as factors that may enrich scholars' understanding of motivational factors conducive to creativity. Although the models discussed here were developed in different theoretical traditions and rarely directly referred to creativity, they allow for three testable predictions related to creativity with implications for the possible.

First, by its nature, creativity is much more approach- than avoidance-oriented. Although, under certain, very specific circumstances, avoidance motivation may be conducive to creativity, in general, creativity is exploratory, depends on an openness to different possibilities, and benefits from an approach motivation. The open question for future research is to what extent both mastery-approach and performance-approach orientations support creativity and what are the boundary conditions for such influence.

Second, while the available evidence suggests that mastery orientation is, generally, conducive to creativity, the role of performance orientation remains ambiguous. Though evidence would suggest performance-avoidance orientation should suppress creative thinking, it is unclear if the same will apply to performance-approach orientation. Similarly, factors that moderate the relationship between performance orientation and creativity should be considered in much more detail. For instance, is creative confidence moderating these links as hypothesized? Is performance

orientation harmful to creativity only among those who do not believe in their creative capacities? These problems require much more systematic and rigorous tests in the future.

Third, and finally, the growing number of studies exploring creative mindsets should incorporate goal orientations into research designs. Based on theoretical premises, mindsets are among the most critical causes of specific goal orientations. Consequently, goal orientations may mediate the relationship between creative growth and fixed mindsets and creative activity. Given evidence for malleability of mindsets, this area of research may be primed for intervention designs that aim at improving individuals' goal orientations to creativity and their resulting potential for creative activity and achievement. And given how intertwined creative mindsets are to a personal philosophy for growth and the possible in one's development, research on future interventions should include a focus on benefits in the realm of the possible for both the self and others (e.g., new career trajectories, growth in an artistic domain, enhanced interpersonal relationships, and professional work that benefits others).

To conclude, goal orientations hold the potential to enrich scholars' knowledge about self-regulation and motivational processes engaged in creative activities and processes, which underly the possible in the future for one's own life and in the life of others. Therefore, future studies in the possible and creativity should include measures of mastery and performance orientations and approach-avoidance orientation to understand better why and when people decide to engage in creative behavior and think about and live in the possible.

Here and Now

Alice Barale
Università degli Studi di Milano, Milan, Italy

Abstract

The concept of “here and now” is central to a large number of psychotherapeutic practices, especially those influenced more or less directly by the emerging popularity of mindfulness (see chapter “Meditation”). In this context, however, the idea of here and now will be analyzed from the point of view of philosophy. This makes it possible to understand two important issues which form a connection between the here and now and the question of the possible: (1) The here and now is never a pure present, but rather a unity between different temporal and spatial dimensions. (2) The true experience of the here and now is not the oblivion of the past and future (or the indifference towards them), but rather a real and active synthesis of these different temporal dimensions. Through this synthesis, the here and now becomes a moment of possibility.

The concept of the “now” has been more investigated in philosophy than that of the

“here,” because it belongs to the field of the philosophy of time and to the question of the instant. In this context, however, the analysis will focus on some authors for whom the “now” cannot be separated from the “here.” This is something that has to be thought through right from the beginning: despite a certain current emphasis on the “now,” “here and now” contains also the “here.” This means that “here and now” does not imply a pure present, but rather something different, which is worth investigating.

This will be done through some examples taken from nineteenth-century philosophy, in particular from Martin Heidegger, Walter Benjamin, Jacques Derrida, and Jean-François Lyotard. This list is not exhaustive, because the aim is not to consider all interpretations of the here and now that have been given, but to consider some significant examples that cultivate a connection between the “here and now” and the possible.

Introduction

The concept of “here and now” is central to a large number of psychotherapeutic practices, especially those influenced more or less directly by the

emerging popularity of mindfulness (see chapter ► “Meditation”). In this context, however, the idea of here and now will be analyzed from the point of view of philosophy. This makes it possible to understand two important issues which form a connection between the here and now and the question of the possible: (1) The here and now is never a pure present, but rather a unity between different temporal and spatial dimensions. (2) The true experience of the here and now is not the oblivion of the past and future (or the indifference towards them), but rather a real and active synthesis of these different temporal dimensions. Through this synthesis, the here and now becomes a moment of possibility.

Definition and History

The concept of the “now” has been more investigated in philosophy than that of the “here,” because it belongs to the field of the philosophy of time and to the question of the instant (see for example North 2018; Hoy 2009; McInerney 1992). In this context, however, certain authors will be analyzed for whom the “now” cannot be separated from the “here.” This is something that has to be thought through right from the beginning: despite a certain current emphasis on the “now,” “here and now” contains also the “here.” This means that “here and now” does not imply a pure present, but rather something different, which is worth investigating.

This will be done through some examples taken from nineteenth-century philosophy, in particular from Martin Heidegger, Walter Benjamin, Jacques Derrida, and Jean-François Lyotard. This list is not exhaustive, because the aim is not to consider all interpretations of the here and now that have been given, but to consider some significant examples that enable an examination of the here and now in its connection to the possible. First, however, it is necessary to say something of the history of the “here and now.”

The expression “here and now” derives from the Latin “hic et nunc,” where it generally indicates an urgent task that needs to be accomplished. This expression’s connection with the

idea of a task is relevant in this context, and it will be necessary to return to it. In ancient Stoicism, “hic et nunc” became an important idea, meaning the necessity of self-awareness or attention (*prosoché*) (see Sellars 2006, p. 133; Sharples 1996, p. 130). Donald Robertson has remarked that while in the current interest in mindfulness, the idea of attention to the present is often associated only to the eastern tradition of Buddhism, one should remember that it was already important in the western philosophical tradition, in particular in Stoicism (Robertson 2013, pp. 165–181). Pierre Hadot characterizes the *prosoché* as “a continuous vigilance and presence of mind, self-consciousness which never sleeps, a constant tension of the spirit” (Hadot 1995, p. 44). This connection between the origins of the concept of “here and now” and the idea of “attention” is also very important and it will be necessary to return to it.

In modern philosophy, the most important investigation of the “here and now” has been given by Georg Wilhelm Friedrich Hegel, at the beginning of the *Phenomenology of Spirit* (Hegel 2018). Hegel’s argumentation is complex but it is worth it to at least say something of it here. “Sensible certainty” or sensation is presented by Hegel as the knowledge that a particular subject has of a particular object, which can be described as a “here and now.” This knowledge of a “here and now” appears as the richest and the truest knowledge that anyone can have. However, if considered, it reveals itself as a mere and empty abstraction. In fact, the “now” does not indicate something stable, but a multiplicity of things that varies at every moment. For example, the “now” can be the night, when someone starts considering it, but it becomes the midday, when the same person goes on with her analysis. In the same way, the “here” can indicate a tree, when someone is in a certain place, but then it becomes a house, when the same subject moves. What remains, therefore, is only the linguistic expression “here and now,” which indicates any here and any now. The “here and now” is not the richest and most concrete knowledge, but rather the most empty and abstract. One could object (and it has indeed been done: see for ex. Maldiney 1973) that the

“here and now” is conceived by Hegel already in linguistic terms, while there could be an impression of a “here and now” that precedes language. However, the important aspect of this analysis, in relation to the issue of the possible, is that the possibility disclosed by the “here and now” can never be immediately attained. Rather, it is always the result of a specific path to be undertaken.

Research on the Here and Now

Martin Heidegger

The German philosopher Martin Heidegger – former student of Edmund Husserl, the father of Phenomenology (which will be addressed shortly) – had a fundamental influence on nineteenth-century philosophy, in particular on the currents of existentialism and hermeneutics. One of Heidegger’s most important books was *Being and Time*, published in 1927. There is a key-term in this book, “Dasein,” which indicates human existence, and is often translated in English as “being here and now” (see for ex. Kisiel 1985, p. 193; Olivier 2003, p. 136). In the current English edition, however, *Dasein* is always maintained in German, except when its two components (“Da” and “sein”) are stressed by Heidegger himself through a hyphen. In these cases, Da-sein is translated literally, as “being-there” (Heidegger 2001).

According to Heidegger, the *Dasein* is intrinsically connected to the question of the possible. The “being here and now” of human existence must be intended as a possibility to be. It is not possible to say “what” the Dasein is, but “its essence lies rather in the fact that in each case it has its essence to be” (ivi, § 4, pp. 32–33).

It is in relation to this possibility of being that the dimension of the moment – which is not called “now” in this book, but rather “Augenblick”: “moment of vision,” according to the literal meaning of the German term, becomes important. The *Augenblick* is what enables a break in the monotone flow of the inauthentic life and face a more authentic way of existence (ivi, § 68a). In the instant, as in a moment of rupture, humans are able to hear the “call of conscience” and

acknowledge their finitude. This is the famous theme of the “being for death,” which does not mean to actively pursue death, but rather to choose death as a possibility that belongs to true human nature.

In their everyday life – this is Heidegger’s thesis – humans tend to forget their finitude and escape from themselves. Their temporal dimension is that of an inauthentic present, of a “making present.” The unauthentic time of the everyday life tends to hide away the *ecstatic* character of time, that is, the unity that every present moment has with past and future. The authentic present, on the contrary, is a reminder of the true temporal nature of humankind: “In contradistinction to the moment of vision as the authentic Present, the inauthentic Present is then called ‘making present’”. Formally understood, every Present is one which makes present, but not every Present has the character of a ‘moment of vision’” (ivi: 388). Heidegger calls “now (Jetzt)” the inauthentic present, opposed to the authentic present of the “Augenblick.” Besides this terminological question, however, Heidegger’s “Augenblick” appears to be quite near to the “nunc” of the Latin “hic et nunc,” also because of the urgency that it expresses. The more authentic life must be chosen immediately, in a moment that imposes itself over the continuity of time in which humans try to forget themselves.

What about the “here,” yet? The spatial dimension of existence is addressed by Heidegger in the first division of *Being and Time*. “Being in the world” is the “basic state of Dasein.” Humans are not *in* the space, but their existence *is* intrinsically *spatial*: “Space is not in the subject, nor is the world in space. Space is rather ‘in’ the world in so far as space has been disclosed by that Being-in-the-world which is constitutive for *Dasein*. Space is not to be found in the subject, nor does the subject observe the world ‘as if’ that world were in a space; but the ‘subject’ (Dasein), if well understood ontologically, is spatial” (ivi, 146). The “there” of the “being-there,” then, is something with which humans are *always already* in relation.

A prior question needs to be raised, however. Is existence a “being there” or a “being here”? The

question is not a merely terminological one. It not only concerns the fact that the German term for existence is “*Dasein*” (“being there”), but also Heidegger’s attempt to consider things from the outside, or at least from a neutral perspective, from his *foundational* aim. Yet there is also another reason for this prevailing of the “there” over the “here,” which has to do with the disappearance, or more precisely the “collapse,” of the spatial dimension itself into the *Augenblick*.

What happens, in fact, to the “there,” when the *Augenblick* comes in which humans can hear the “call of conscience”? The emotional state that corresponds to this moment is that of anxiety (ivi, § 68b). Anxiety shows the “being-in-the-world” as deprived of its sense: in anxiety, the everyday world collapses: “In anxiety the usable stuff in the environment, and in general all intraworldly entities go under. The ‘world’ has nothing to offer any more . . . Everyday familiarity collapses. *Dasein* becomes individualized, but as being-in-the-world. Being-in acquires the mode of not-being-at-home.”

In the moment of rupture that the *Augenblick* represents, the “there” (or the “here”) of the world goes under. This corresponds to the fact that space has to be reduced to time, as the following paragraphs of *Being and Time* explain. Every place can constitute itself only inside a world, and the world can constitute itself only through the original temporality of the *Dasein*. If *Dasein* is translated as “here and now,” then, it is necessary to pay attention to the fact that the “weight” of the two terms is not the same, but the “now” prevails over the “here” and tends to let it “go under,” or at least to withdraw from it. This means that the possibility disclosed by “being here and now” is only an internal one: it concerns only the “now,” while the world outside (the “here”) is left to itself.

Walter Benjamin

Walter Benjamin is a German philosopher who lived in the same period as Heidegger. His thought, nevertheless, is very different from that of the latter, even opposite from certain points of view, to the point that Benjamin once declared his intention of “destroying the Heidegger” (Benjamin 1982). Like Heidegger, Benjamin thinks of

the moment (which he calls the “now”: “Jetzt”) as an interruption of the normal course of time. The nature of this interruption, however, is completely divergent from Heidegger’s and opens up a very different way of relating to the question of the possible and possibility. It is not by chance that this interruptive instant is called “jetzt” by Benjamin, which is the name that Heidegger gives to the inauthentic time, as noted above. In fact, Benjamin’s “now” does not prevail over the “here” of the everyday world, as Heidegger’s *Augenblick* does. Rather, it is deeply intertwined with the “here.” In Benjamin’s thought, “here” and “now” pass one into the other in some ways and this opens up a very particular relationship to the question of possibility, as it will be shown.

Benjamin’s use of the expression “here and now” refers to the “aura” of the artwork (Benjamin 2008). The “aura” is the “here and now” of an artwork (ivi), its “unique” and unrepeatable appearance. Benjamin’s famous thesis is that when art, with the advent of photography and film, becomes reproducible, its “aura” declines. This is not something negative, according to Benjamin. On the contrary, it has a liberating aspect. The decline of the “aura” coincides with a decline of the idolatrous aspect of the artwork, that is, the appearance of the artwork as something that can neither be changed nor criticized. The decline of the aura opens up a new “space of play” in which every appearance can be transformed and again called into question at every moment.

This contributes to highlight the more positive idea of “here and now” that can be found in Benjamin’s work. In order to understand this second idea of “here and now” and the new possibilities that it implies, it is useful to begin with Benjamin’s concept of the “now.”

Benjamin gives his first interpretation of the “now” in a fragment of circa 1920 (Benjamin 1991, pp. 45–46). Here, Benjamin speaks of a “now of recognizability” (“Jetzt der Erkennbarkeit”). The world, Benjamin explains in this text, cannot be known in an a-temporal way. Human knowledge of things has a moment, a determinate “now,” in which these things can be known. It is necessary to destroy the illusion of the “atemporal value” of things and to show how they

“constitute themselves” only in the moment (“the now”) of their recognizability.

The “now of recognizability,” therefore, is a “logical time” (ivi). This is a very important aspect: the moment of which Benjamin speaks is not simply something that happens, according to the natural course of time; it is a moment *of knowledge*. Knowledge, in some way, freezes the usual course of time and gives birth to a moment in which things have a particular aspect. The presence that the “now” allows, therefore, is the presence of knowledge to itself. This marks an important distinction from the interpretation of the “here and now” that will be given, for example, by Jacques Derrida, which will be considered shortly.

In this arrest that the “now of recognizability” permits, time and space transform one into the other. This is also something that already emerges in Benjamin’s early work, long before his more famous idea of “dialectical image.” In *The Origin of German Trauerspiel*, the baroque drama (the “Trauerspiel” of the title) is intended precisely as a representation of time (human history) as space (the theatre scene) (Benjamin 2020). To freeze time and to make it become space, or image, is a necessity for knowledge. On the other hand, this can happen only for an instant, because every image that can be had of the world is incomplete and awaits another image.

This instantaneous character of knowledge is what Benjamin expresses in his famous idea of the “dialectical image.” In the dialectical image, Benjamin writes, past and present come together “in a flash”: “It is not that what is past casts its light on what is present, or what is present its light on what is past; rather, image is that wherein what has been comes together in a flash with the now to form a constellation” (Benjamin 1999, p. 463). This instantaneous unity between present and past is also a very relevant aspect of Benjamin’s idea of the “here and now.” In fact, what Benjamin wants to say is that there is not one “real” image of the past. Rather, past is an infinite source of possibilities, which can and must be grasped in the present.

In the “here and now” of the dialectical image, therefore, different temporal dimensions converge and transform each other, giving birth to a

complete, albeit fugitive, presence. Yet why is the past so important in relation to Benjamin’s idea of the here and now? It is in relation to this question that Benjamin’s idea of the “here and now” also acquires an ethical value. Benjamin’s idea is that all that has been forgotten and misrecognized in the past awaits justice in the present. He writes, therefore, that “our coming was expected on earth” (Benjamin 2006, p. 290; see Desideri 2015). This has to do not only with the historical past, but also with the past of our everyday perception of the world. There is so much in what we perceive, much more than we can tell and express every time. Therefore, it is necessary to go back to it and do justice to what has been forgotten or misrecognized. Also, the fact that this past we must return to is waiting for us is very important in relation to the issue of the possible, because it means that the possible is already there, and it is our duty to give voice to it.

Benjamin calls “Messianism,” this idea of a redemption of the past in the present. The word comes, of course, from the Jewish tradition, to which Benjamin, as a German-Jew, belonged. The reference to a Messiah, however, must not call to mind a salvation that comes at the end of time, beyond history. In fact, the salvation of the past takes places at every moment again.

Derrida

Jacques Derrida is one of the most important philosophers of the second half of the nineteenth century, father of the so-called “Deconstructionism” (see Norris 2002). Derrida’s investigation of the “here and now” takes up, in a certain measure, the critique of Heidegger to the inauthentic present and transforms it in a very interesting way (on Heidegger’s influence on Derrida see Spivak 1976). Heidegger’s idea, as noted above, was that humans tend to remove the present’s connection to the past and the future, in order to *make* everything *present* and manageable. This way they misrecognize an important difference: the difference between the *beings* and the *being*. Derrida refuses Heidegger’s idea of being: there is not such an original plenitude of being that precedes the unstable life of beings and that can be attained through the choice of a more authentic existence

(what the Heideggerian *Augenblick* permits, as noted above). However, there is indeed a tendency, within the history of philosophy, to give a primacy to the dimension of the present over past and future, and to the presence over the absence. This is what Derrida calls the “metaphysics of the present.” The first move of Derrida’s philosophy, therefore, consists in a critique of the “now.” There is a second move, however, that implies a recuperation of the “here and now,” in a different sense. In order to understand Derrida’s idea of the “here and now,” and its connection to the issue of the possible, it is therefore necessary to divide the analysis into two points: a. the critique to the metaphysics of the present and b. the importance of the “here and now.”

a. *The critique to the metaphysics of the present.* A fundamental point of departure for Derrida’s critique of the “now” is an essay by Edmund Husserl entitled *The Phenomenology of the Internal Time-Consciousness*, published in 1929. In this text, the German philosopher investigates the temporal structure of experience. According to Husserl, the “now” can never be isolated from the past and the future (Husserl 1964, §19). The image that Husserl uses to represent the present is that of a comet with its tail: the “now-apprehension is [...] the nucleus of a comets tail of retentions” (Husserl 1964, §11). This is something that becomes very important for Heidegger, as noted above, who calls this “extended” structure of time its “ecstatic” character. What Derrida focuses on, however, is the fact that the present remains, nevertheless, the prominent dimension of Husserl’s analysis. It could not be otherwise, because Husserl’s phenomenology is intended to be an analysis of the “phenomenon,” that is, what immediately appears to conscience, before being elaborated upon in language and in memory. The “living present,” therefore, is conceived as the center from which all memories and expectations are organized, their “*source-point*” (ivi; italics mine).

In order to maintain this primacy of the “now,” Husserl makes a very precise distinction between “retention” and “representation,” that is, between the immediate sensory traces and the reproduction, after longer time, of what was perceived.

Derrida’s move consists in showing that such a “radical difference” does not exist. To perceive is already to retain, because what is perceived is not there anymore. This is a consequence, according to Derrida, of what Husserl himself has shown, when he explained the “continuity” that exists between “the now and the not-now, perception and non-perception” (Derrida 1973, pp. 64–65).

To discover this presence of an absence inside presence itself is very important, from a philosophical point of view, because the entire history of philosophy is characterized, according to Derrida, exactly by this “privilege of a present-now,” as an attempt to find an “origin” or “foundation” (Derrida 1973, p. 61). Derrida applies this type of analysis to a number of great thinkers, like Plato, Rousseau, Lévi-Strauss, and Hegel. He intends to show that every time these authors searched for the present (the “now”), they found also the absence (the “not-now”) and the link between presence and absence. This is crucial, according to Derrida, because precisely this link between presence and absence is the locus of a generative movement. It is from the connection between the presence of the sense and its absence that a new sense can arise time and again. In this way, it is possible to come closer to the second movement in Derrida’s interpretation of the “here and now,” the one that implies a valorization of this concept.

b. *The valorization of the here and now.* In order to understand this passage from a critique of the “now” to the importance of the “here and now,” it is useful to briefly consider Derrida’s idea of writing. The privilege of the present inside the history of philosophy expresses itself very clearly in the primacy of speech over writing. Speech has always been privileged over writing because it gives the impression of an immediate link between sound and meaning, signifier and signified. Writing deconstructs this illusion and introduces an element of indecidability within language: “Writing displaces the proper place of the sentence, the unique time of the sentence pronounced *hic et nunc*” (Derrida 1998, p. 281).

One of the main and most well-known concepts through which Derrida has expressed this displacement of meaning is that of “différance,” which means at the same time “difference” and

“deferral.” Différance does not simply indicate the system of differences that constitutes language – according to the idea of structuralism, which is another important point of departure for Derrida’s critique – but it is also the “*generative movement*” that gives birth to them and puts them in motion again and again (Derrida 1982, p. 27; italics mine).

There is, therefore, a temporal moment in which differences and, consequently, meaning emerge. This is the “here and now,” the necessity of which Derrida underlines. One of the main messages of his philosophy, in fact, is that it is not possible to gather the meaning of something once and for all (as the metaphysics of presence would like to do). For exactly this reason, it is necessary to return to things in their singularity every time, to go back to their “here and now”: “No différance without alterity, no alterity without singularity, no singularity without *here and now*” (Derrida 2006, p. 37: my italics). On the other hand, since every present is essentially inhabited by an absence (“haunted” by it, as Derrida writes in *Spectres de Marx*), what can be discovered in the “here and now” is necessarily something that is not yet there: a “here, now, tomorrow” (ivi, back cover). In this way, the idea of “here and now” acquires a new character. While the “here” remains a “here” – marking the importance of singularity, as a locus of meaning that must again be questioned time after time – the “now” becomes a “now and tomorrow”: a present that is at the same time an absence and a future. An “impossible” that is the only “condition of possibility” (Derrida 2005, p. 47; see also Derrida 1992).

Jean-François Lyotard

Jean-François Lyotard has become famous as the philosopher of Postmodernism (see Lyotard 1984). In his investigation of the concept of the sublime, Lyotard proposes what he considers as a radically new interpretation of the “here and now” (Lyotard 2012; see also Lyotard 1994, 1999). He starts considering the titles of a number of works by the American painter Barnett Newman, who worked on the representation of the sublime (one of his works is called “Vir Heroicus Sublimis”;

see also Newman 1991), and he notices that the expressions “here” and “now” recur many times. There is a connection, therefore, between the experience of the sublime and the “here and now.” How is this connection to be understood?

The sublime is an aesthetical category that was elaborated upon during the eighteenth century, when an ancient essay by a certain Pseudo-Longinus entitled “Peri Hypsous” (“On the sublime”) was translated into French by Nicolas Boileau (see chapter ► “Aesthetics”). From that moment on, a great discussion arose on this concept. The sublime became something different from and even opposite to the beautiful, because it implied not only a sensation of pleasure, but also an impression of fear and pain. Sublime is, for example, the infinite darkness of night, or the spectacle of a terrible event, like a shipwreck. According to Immanuel Kant, from whom Lyotard’s analysis begins, the sublime has to do with “something that can’t be shown or presented” (Lyotard 2012, p. 531; Kant 2009, § 23). How can it be connected, therefore, to the “here and now”?

Lyotard’s answer is that what cannot be shown or presented is precisely the “here and now.” The “here and now” is the fact that something happens, and this fact precedes every knowledge that anyone can have of “what” happens: “The inexpressible doesn’t reside in an over there, in another world or another time, but in this: in that something happens” (Lyotard 2012, p. 533; see also Lyotard 1989, p. 247). The fact that something happens is beyond the reach of human thought. Therefore, Lyotard writes that the “here and now” is “a stranger to consciousness” (Lyotard 2012, p. 531).

The task of art is to “bear witness” to this inexpressible fact, the fact that something happens (ivi: 533). What happens, in this case, is the painting: “Here and now there is this painting, rather than nothing, and that’s what is sublime” (ibidem). It is in particular the art of the Avant-garde that shows, according to Lyotard, this inexpressible character of the event: “guarding the occurrence ‘before’ any defense, any illustration, and any commentary... this is the rigour of the Avant-garde” (ibidem). The “here and now” that art

brings to light, according to Lyotard, is what comes “before” thought and before conscience. Therefore, the “here and now” has an *interruptive* character, it breaks every flow of time and interpretation: “Presence is the instant which *interrupts* the chaos of history and which recalls, or simply calls out that ‘there is’, even before that which is has any signification” (Lyotard 1989, p. 247, my italics).

Is it really possible, however, to divide this moment that comes “before” knowledge from its subsequent elaboration into form and conscience (see on this Benjamin 2015)? And moreover, doesn’t this attempt to divide the two moments imply the risk of hypostatizing this arising moment, of fixing what cannot be fixed, of giving a name to what does not yet have a name? It will be necessary to return to these questions in the next section.

Conclusion: Here and Now and the Possible

Some general traits of the “here and now” can be drawn from the philosophical interpretations of it that have just been considered.

First of all, as has already been noted about the Latin “*hic et nunc*,” the here and now marks the moment and the space of a *task*, which shows itself with *urgency*. The “here and now,” then, is not something that is already there, as it is said in some trivial versions of popular wisdom (“don’t worry too much and just live here and now. . .”). The “here and now” is a possibility that has to be grasped, with effort and commitment. This is also evident from the character of rupture attributed to the “here and now” in all considered authors. The “here and now” breaks with the normal course of time (see on this Friese 2001). For this aspect of change and subversion, the here and now has a connection to the concepts of creativity and awe (see corresponding sections).

This exceptionality, however, must not lead one to think of the “here and now” as just a single, or rare, isolated moment. This misunderstanding applied very often, for example, to Walter Benjamin’s idea of “*jetztzeit*” (see for ex. North 2018). The *jetztzeit* (and so the “here and now”) can and

must take place at every moment and in every place. Creativity and change are something that must concern every instant and every aspect of life. This does not mean that the possibility opened up by the here and now is warranted. As Benjamin shows, the here and now is at the same time something that must be grasped with intellectual effort and tension and something to which a person must be open and that she must be ready to find on her way. Both attitudes are necessary: control/commitment and abandon/receptivity; their unity is necessary (see on this the chapter ► “Aesthetics”).

Another important trait that was confirmed by the analysis of these different interpretations of the “here and now” is the relevance of the “here.” This means that the “here and now” is not a purely internal moment (where time is something merely internal to the subject), but it is something that has to do with one’s relation to an external world. This is a necessary condition if one does not want to subsume, as Heidegger does, the “here” under the “now.” The possibility that the “here and now” involves is a possibility that concerns the human relationship to the world.

Another question arises from the philosophical interpretations of the “here and now” that were previously considered. The relationship between the here and now and the possible, the new chances opened up by this time of rupture, has been analyzed. Yet in some of the considered authors, the here and now seems to also have a relationship to the *impossible*. It is the case, as noted above, of Derrida’s philosophy, according to which this moment of change and attention is an “impossible possibility.” However, this is not the only viable interpretation of the link between possibility and impossibility that characterizes the here and now. According to Benjamin, for example, the here and now is the moment of a very present chance, which is indeed inexhaustible – therefore every “here and now” has to give way to other moments/spaces of realization.

One more issue is the relation that the “here and now” has to thought and knowledge. There is an element of immediacy in the here and now and in the possibility that it discloses. It is this immediacy that makes Lyotard state that the “here and now” precedes every attempt to express it through

language and meaning. Is it really possible, however, to think of the here and now as something that precedes thought? Or is it rather the opposite, and thought should be considered as always having a relationship to something that it does not control, with a “here and now” that constitutes its limit but also its greatest condition of chance and possibility?

Heuristics

Enrico Rubaltelli

Department of Developmental Psychology and
Socialization, University of Padova, Padova, Italy

Abstract

Heuristics are strategies that allow individuals to reach a conclusion for themselves or to fill a gap when information is not available. In the past 25 years or so, the empirical study of heuristics showed that these strategies are ingrained in the functioning of the human brain and central to processes like problem-solving and judgment and decision-making. As a result, heuristics have become a fundamental feature of psychological theories and challenge the traditional vision of analytical, rational thinking and information processing that was proposed in other disciplines (e.g., economics). Past research has shown that there is an array of heuristics that individuals employ to cope with the complexity of the environment in which they are living. These strategies allow to make quick evaluations of events and stimuli that can inform decision-makers about what to do when the outcomes are uncertain, information is incomplete, or time is constrained. Heuristics are also instrumental to save cognitive resources by engaging in a tradeoff between the quality and the effort required to make a decision. A consequence is that heuristics can bias thinking and reasoning, although they are also instrumental to allow the human brain to react with high flexibility and speed. The debate is still open on whether the impact of heuristics on our reasoning is positive or not, and a wide range of debiasing techniques has been developed over the years (228).

Heuristics · Decision-making · Judgment · Bias · Thinking · Reasoning · Intuition

Introduction

Despite what most laypeople believe, human **decision-making** is not always driven by **conscious** thinking and is often impacted by cognitive limitations and environmental constraints. As a result, the impact of **unconscious** processes becomes pervasive in many contexts (Kahneman 2011).

Heuristics have been found to be important, intuitive strategies that people use when making **judgments** and processing information. Although the term was introduced by Simon (1990), it became widely used in psychological literature thanks to the work of Tversky and Kahneman. These authors were the early proponents of the heuristics and **biases** program and defined heuristics as strategies that “reduce the complex task of assessing probabilities and predicting values to simpler judgmental operations” (1974, p. 1124). Similarly, the Oxford English Dictionary defines heuristics (in psychology) as: “designating or relating to **decision making** that is performed through intuition or common sense.” Research on heuristics has now spread to many different fields beyond cognitive sciences and psychology. The early research on heuristics has been applied with important implications in disciplines like finance (Hirshleifer 2015), medicine (Stiggelbout et al. 2015), law (Brest and Krieger 2010), policymaking (Thaler and Sunstein 2008), and **risk** perception (Slovic 2000) among many others.

There are several ways in which the study of heuristics connects with the investigation of the possible. Certainly, heuristics contribute to people’s subjective perception of the world and their lives. Similarly, heuristics impact the way people assess the outcomes of their choices and the chances they have to achieve them in the future. In a sense, since heuristics processing is quick, intuitive, and based on our experience, it creates different possible worlds and perceptions depending on who is assessing a particular situation. Different individuals may hold different beliefs or opinions even when the information is the same. However, we also know that heuristics

lead to systematical biases that may actually get people stuck on a specific worldview and, to some extent, unable to fully explore other possibilities.

The next section provides a theoretical and historical background explaining how psychologist came to realize the role of heuristic in human **decision-making**. Subsequently, an overview of the main heuristics will be provided, followed by a brief review of research in fields outside psychology (e.g., finance, law, and medicine). Finally, the concluding remarks will provide a brief overview of **debiasing** techniques.

Theoretical and Historical Background

For a long time, researchers focused on how people process and use information in order to make optimal decisions. Critically, this approach was based on the assumption that decision-makers were weighing information and applying **conscious deliberation** to choose the alternative with the highest **expected value**. Economists were at the forefront of this approach devising a set of principles that individuals should follow in order to maximize **expected value**. Although these principles required exceptional computational skills, it was assumed that people were deciding “as if” they were complying with them. As a result, decision quality was measured by looking at people’s choice regardless from the correctness of the procedure followed to reach it.

This approach was challenged by Simon (1990) who proposed the concept of “**bounded rationality**,” referring to the fact that decision-makers are often constrained by several factors, such as limited cognitive resources, incomplete information, and time pressure. Simon’s work contributed to shift the focus of research more on the procedure followed by decision-makers rather than just the correctness of their choices. Within this framework, he proposed the “**satisficing principle**” whereby individuals make a tradeoff between the quality of their decisions and the effort required. In other words, because of cognitive and environmental limitations, decision-makers explore the possible

alternatives to a problem up to the point in which the effort required to search for additional information exceeds the possible improvement in the quality of the decision.

Subsequently, the term **heuristics** was used by Tversky and Kahneman to refer to the intuitive strategies people use when assessing probabilities and outcomes (see Gideon and Teigen 2004). Like in Simon’s approach, Tversky and Kahneman showed the existence of a series of strategies that humans use, mainly in an intuitive way, to simplify judgments that would be otherwise too complex or require too much time to retrieve all relevant information. However, on many occasions, these simplified strategies are generalized even to situations in which the decision-maker could use rather straightforward statistical or logical principles. Initially, Tversky and Kahneman described three main **heuristics**: **representativeness**, **availability**, and **anchoring** and adjustment.

Representativeness Heuristic

People use the **representativeness** heuristic when they have to determine whether a stimulus A belongs to the category B or whether the event A has originated from process B (Tversky and Kahneman 1974). To answer this type of questions, people look at how representative event A is of process B (or category B). Instead of using actual probabilistic information, they use similarity as a proxy of the relationship between two events. If A closely resembles the prototypical exemplar of category B, it is inferred that it must belong to that category. Several examples of **representativeness** have been reported. Empirical research has shown that, because of the **representativeness** heuristic, people become insensitive to base rate frequency. In an early study, Kahneman and Tversky presented the description of a fictitious graduate student (Tom W.). A first group of participants, who was not presented with the description, was asked to rank order nine fields of study based on their best guess of the percentage of students enrolled in the first year of graduate

school (base rate group). A second group was presented with the description and asked to rank order the nine fields of study in terms of how similar a typical student in each of them was to Tom W. (similarity group). Finally, a third group was asked to rank order the nine fields of study based on the likelihood that Tom W. was a graduate student in each of them (prediction group). Results showed that participant's predictions were more closely related to the results found in the similarity group than in the base rate group. In other words, answers in the prediction group were overly influenced by the description of Tom W., whereas the distribution of students across the different fields of study was not used to predict which program he was enrolled in.

A second important implication of the **representativeness** heuristic is people's insensitivity to sample size. Based on this effect, decision-makers tend to apply the rules of probability even to samples that are too small in size, hence not representative of a population. For instance, the average height of a sample of ten men will be judged based on the average height in the population of men. However, ten men are a very small sample and not representative of the whole population. As a result, the average for that sample is likely to diverge compared to the average found in the population. Kahneman and Tversky presented three groups with the question regarding the likelihood to find an average height above 6 ft in a group of men. Each group was provided with a different sample size: 1000, 100, or 10 men. Results showed that sample size had no effect on responses to a question asking the probability of obtaining a height above 6 ft (Tversky and Kahneman 1974). The **representativeness** heuristic leads also to misconceptions of chance. For instance, when tossing a coin, people consider the sequence H-T-H-T-T-H to be more likely than H-H-H-T-T-T, since it resembles more the characteristics of a random series of events. However, for every coin toss, there is always a 50–50 chance to get either heads or tails. As a result, in a short series of tosses, it is entirely possible to get several heads or tails in a row,

despite the fact that a similar sequence of events does not resemble our intuitive idea of randomness.

Although the **representativeness** heuristic can be a good approximation of the correct answer in many contexts, it can lead people to feel overconfident about their inferences (Tversky and Kahneman 1974). This happens because probabilities are almost completely assessed based on the degree of similarity between the stimulus (e.g., Tom W.) and the category (e.g., his field of study), with little consideration for base rates or sample size. Finally, **representativeness** can lead people to be unaware of regression to the mean. This principle states that extremely positive or negative events, once they are measured again, are likely to converge toward the mean value for their population. However, people tend to infer that an extreme event is representative of an extreme phenomenon. When thinking about climate change, individuals may find difficult to understand that global temperature is increasing because not every day the weather is warmer than usual. Because of regression to the mean, after a very hot day or week, it is likely that the temperature moves back toward the mean.

Availability Heuristic

Availability is used to judge the frequency of an event and is based on how easy it is to retrieve instances of that event (or similar ones) from memory. This heuristic works particularly well when people assess the frequency of events they are familiar with. However, it can lead to mistakes when applied to events that are not well known (Tversky and Kahneman 1974). The **availability** heuristic has a significant impact on people's **risk** perception. On the one hand, if many instances of a disease (e.g., friends that suffered of cancer, news in the media, and so on) come easily to our mind, then we will be likely to overestimate its rate of occurrence in the population. On the other hand, if we find it difficult to come up with instances of people who died struck by lightning, we will underestimate this cause of death. Research showed that the ease with which

instances come to mind is influenced by familiarity with the event, but also its salience (e.g., seeing the event first hand rather than being exposed in the media) or recency (e.g., being directly or indirectly exposed to a recent event).

An implication of the **availability** heuristic is that decision-makers can be sensitive to what Tversky and Kahneman call “the effectiveness of the search set.” In a study, people were asked to judge whether it was more likely for an English word to start with “r” (e.g., read) or to have “r” as the third letter (e.g., more). When confronted with a similar question, people try to retrieve from memory words starting with r or having r as the third letter. Since it is easier to come up with words that start with a specific letter, participants judged words with r as the first letter more frequent than words with r as the third letter (although the opposite is actually true). Finally, two additional implications of the **availability** heuristic are **biases** of imaginability and the illusory correlation. In many occasions, people must assess the frequency of events by imagining examples of these events. For instance, an entrepreneur may want to assess the likelihood of potential risks that could impact his/her business. To do so, he/she must first come up with a list of those events. Likely, the list will include risks that came up easily in the entrepreneur’s mind, and these will be considered more likely to happen than those he/she had more difficulty to imagine. Finally, illusory correlation regards the assessment of co-occurring events (Chapman and Chapman 1967). According to Tversky and Kahneman (1974), the **availability** heuristic induces people to perceive illusory correlations based on the strength of the association between co-occurring events. When the association comes up easily in people’s mind, they are likely to see a correlation and to infer a correlation between the events.

Anchoring and Adjustment Heuristic

The third heuristic described by Tversky and Kahneman (1974) is **anchoring** and adjustment. This heuristic is used when people are asked to

make an estimate. On these occasions, decision-makers often anchor their response to a specific value and adjust it toward what they think the correct answer should be. For instance, imagine the questions “Was Gandhi more or less than 144 years old when he died?” and “How old was Gandhi when he died?” When people are answering to the second question, the number presented in the first question primes them and leads them to think about it. They then adjust their response in the direction of what they think is the correct answer and stop once they are unsure whether it is safe to move further away from the anchor or not.

Anchoring is an interesting heuristic since it involves different processes depending on how estimates are elicited. The **anchoring** and adjustment process described above is based on an intuitive adjustment process, but researchers have demonstrated that **anchoring** can arise from deliberative thinking as well (Epley and Gilovich 2006). When people are asked a question like “What is the boiling temperature of water at the top of Mount Everest?”, they easily self-generate and anchor (e.g., water boils at 100 °C). They also understand that this anchor is wrong, since water boils at a lower temperature at altitude than at sea level. Therefore, when answering such a question, people engage in a deliberative thinking process whose goal is to find arguments in favor of moving away from the anchor. When they do not find any additional argument to move further, they stop and infer that the correct answer is the value they have reached.

Affect Heuristic

Following Tversky and Kahneman seminal work, other **heuristics** have been described in the literature, some of which will be mentioned in the next section. One important, intuitive strategy that has been proposed more recently is the **affect** heuristic (Slovic et al. 2002). This heuristic showed to be relevant both because it advanced our understanding of how people make decisions and because of the applied implications it spurred (Kahneman 2011).

According to the **affect** heuristic, “representations of objects and events in people’s minds are tagged to varying degrees with **affect**” (Slovic et al. 2002, p. 400). For instance, Slovic and colleagues found higher ratings of attractiveness for a gamble offering 7/36 to win \$9 and 29/36 to lose 5¢ than for a gamble offering only a gain (7/36 to win \$9). Similarly, only a minority of participants chose to play the gamble offering only the win, whereas the majority chose to play the gamble offering both the win and the small loss. In other words, the decision to play the gamble was influenced by how attractive people perceived it. Specifically, these findings are interesting because a small loss made the win easier to evaluate and, consequently, induced people to experience a more positive feeling than when the 5¢ loss was not present.

Research on the **affect** heuristic has shown that people perceive **risk** based on their affective reactions toward specific events (e.g., terrorist attacks), substances (e.g., pesticides), or activities (e.g., mountaineering). In particular, these findings have shown consistently that individuals perceive a negative correlation between risks and benefits. On the one hand, high benefits induce positive affective reactions and, as a result, to infer that **risks** are low. On the other hand, high **risks** induce negative affective reactions and, as a result, to infer that benefits are low. For instance, a person who supports building a nuclear power plant in their country would likely see this source of energy as associated with high benefit (e.g., cleaner than coal) and low **risk** (e.g., the last generation of nuclear reactors is very safe). However, a person that opposes the construction of the nuclear power plant is likely to see high **risk** (e.g., even small accidents can have huge consequences) and low benefit (e.g., there are other ways to produce clean energy). Finally, people’s judgments and behaviors do not depend exclusively on the valence (positive or negative) of the feelings they experience toward the mental image of a stimulus but also on the precision of such image. As a result, activities that are easy to imagine, familiar, or widely reported in the media are more vivid and induce stronger affective reactions, therefore impacting

behavior in a more decisive way (Slovic et al. 2002).

Applied Work on Heuristics

Work on **heuristics** and **biases** has been central for the application of psychological research to many domains outside psychology. As a result, it seems important to briefly describe some of these applications as well as specific **heuristics** that this research allowed to identify.

Economics was one of the first fields to be influenced by Kahneman and Tversky’s work, mainly thanks to a host of authors who realized the importance of incorporating human psychology in fields like consumer behavior, management, and finance. Together with other findings in psychological research (e.g., prospect theory; Kahneman and Tversky 1979), the study of **heuristics** in the economic field led to the emergence of disciplines like **behavioral economics** and **behavioral finance** (Hirshleifer 2015).

In finance, **heuristics** have been shown to influence investors’ decisions regarding buying and selling stocks or how to manage their portfolios. Among the **heuristics** described so far, **availability** can be identified when people invest in familiar companies, famous brands, or companies that have been praised frequently in the media. In contrast, investors tend to avoid stocks that do not come easily to their mind. Furthermore, investors may expect that investing in a large, popular company should yield high returns just because it is representative of a successful business (Shefrin 2002). However, small companies may yield higher returns than large ones because they are riskier. Consistent with this conclusion, many investors tend to perceive a negative correlation between **risk** and returns in the financial markets, although one of the most famous rules of finance is the positive correlation between risk and returns (on long time horizons, investors should be rewarded for taking a risk). Similarly, people are more likely to invest in admired companies because they associate them to high expected returns and low **risk** (Statman et al. 2008).

Finally, portfolio diversification is often made naively, and some authors have demonstrated the existence of a **1/n heuristic**. This heuristic suggests that investors divide their portfolio in equal parts regardless of the number of alternative investments they are offered. If there are only two funds, they will invest 50% of the portfolio in the first fund and 50% on the second. However, if the funds available are four, they will invest 25% of the portfolio in each of them (Thaler 1999). Other **heuristics** similar to the 1/n have shown how difficult it is for investors to understand portfolio diversification. This difficulty makes also investors vulnerable to potentially irrelevant factors such as the array of alternatives they are presented with. Finally, in financial markets, reliance on the **anchoring** heuristic is a pervasive strategy since one of the main tasks of investors is to predict future values. They accomplish this task by **anchoring** their estimates to the current values of the market, although this is not necessarily a good strategy (Kahneman 2011).

Heuristics have also been shown to have a significant impact on the way people assess risk. As stated above, the **affect** heuristic is responsible for people's inference that **risk** and benefit are negatively correlated (regardless from whether this is actually true or not). Furthermore, some stimuli are more representative of a **risk** than others (e.g., explosions vs. air pollution). Similarly, instances of vivid events (e.g., terrorist attacks) are more easily recollected from memory, leading to an overestimation of their frequency and consequences. In addition, many people are influenced by an optimistic bias (Slovic 2000) and believe that a particular negative outcome will not happen to them. For instance, they may find justifications to rationalize why a tornado will never hit their town despite the fact that a nearby one was hit recently. Finally, people evaluations are influenced by how they think about a **risk** that has a cumulative effect on their health. For instance, it makes a difference if people judge the **risk** of smoking by assessing it one cigarette at a time rather than considering the cumulative impact of all the cigarettes they smoked in the last 10 years (Slovic 2000). In this latter case, individuals are

more likely to realize how big a **risk** they are facing.

In law, several of the classical **heuristics** have been identified. For instance, litigations are a natural setting in which the **anchoring** heuristic is used (and studied; see, Guthrie et al. 2001). Research have shown that people are more likely to accept a \$12.000 final settlement when the starting offer was \$2.000 rather than \$10.000. This is because the low initial offer makes the final amount of money look more generous compared to when the litigation started from a higher offer. In other words, people do not evaluate the final offer based on its absolute value but in relation to a reference point they are anchored to. Similarly, studies with mock juries found that judges award a significantly higher amount of money when the request from the plaintiff's lawyer is \$500.000 rather than \$100.000. As a result, even the request of silly damages can have an effect on the decision of the judge. This should not happen because judges should award damages based on the case at end rather than **anchoring** their decision on the request from the plaintiff's lawyer. In this domain there are also numerous demonstrations of the **representativeness** heuristic like in cases when judges seem to have a preference for individuating evidence (e.g., eye witness testimony) rather than statistical evidence (e.g., base rates; Guthrie et al. 2001). Furthermore, in court, base rates are often neglected when assessing scientific evidence. For instance, when a scientific test indicates that there is only a 3% chance of an error, most people are inclined to think that the suspect must be guilty. However, the relevance of this information depends on the dimension of the population. For instance, 3% in a population of 4 million people corresponds to 120,000 individuals. It is hard to find the suspect guilty when there are so many other individuals who could have been responsible for that crime (assuming that no additional information is available).

Finally, a large body of work showed how **heuristics** influence judgments of both doctors and patients (Stiggebout et al. 2015). Furthermore, research has showed specific intuitive strategies related to how people perceive pain. Redelmeier and Kahneman (1996) proposed the

peak-end rule, suggesting that people judge the total pain experienced during a painful medical exam (e.g., colonoscopy) by recollecting the most painful moment of the procedure and how they felt toward the end. This heuristic has the striking consequence that increasing the length of the colonoscopy by adding a low pain stage at the end makes people recall it as less unpleasant. This happens despite the fact that the actual pain is higher for the longer procedure than for the shorter one, when it is measured asking the patient, every 60 s, how much pain he/she feels.

At the applied level, the study of heuristics is tied closely with the investigation of the possible. Depending on what is more accessible in people's minds and depending on their experiences, some alternative worldviews or perceptions of the self will be more likely than others. As a result, we can conclude that these psychological processes shape people's perception of complex events that are happening in the world around them (or thoughts they have in mind). As a result, they become the starting point people use to explore the possible, be it alternative futures (e.g., how do I feel about the stock market? Will it go up next year?), or alternative pasts (e.g., what if I accepted that work abroad when I was younger?), and so forth. Intense positive feelings may provide an affective tag to assess future possible events and make them look better or more likely than they actually are. Similarly, if several examples of a negative event come easily to mind, a person may conclude that a different choice would have yielded a worse outcome than what had actually been done. In both cases, people will be more likely to engage on specific dimensions of the possible future or past rather than others that do not elicit the same strong feelings or whose examples do not come to mind easily enough.

Conclusion

Although the literature on **heuristics** shows that people make many errors in their judgments, these strategies serve a purpose in helping people make quick evaluations about a world that is complex

and uncertain. More importantly, **heuristics** are not necessarily linked to errors in estimates but allow people to reach sufficiently good results on many occasions. The debate is still open on whether **heuristics** are mostly useful to make good decisions or mostly a source of errors and **biases** (Gigerenzer et al. 1999).

In any case, a large literature has investigated ways to debias people's judgments. Within the debiasing literature, the two main approaches are the following: (i) experts can help create decision contexts that are designed to improve decision quality (e.g., Thaler and Sunstein 2008); otherwise, (ii) it is possible to teach decision-makers a set of techniques to overcome heuristic thinking (Larrick 2004). This second approach is the most relevant here and relies on different debiasing strategies, such as motivational processes based on incentives or accountability and cognitive strategies to lead the decision-makers to use deliberative thinking (e.g., "consider the opposite"; use of frequencies rather than probabilities).

Debiasing techniques are also an interesting test ground to assess how heuristics influence people's thinking about what is possible. It would be interesting to assess how much these procedures can help individuals detach from their intuitions and investigate what is possible without constraints. We could argue that through debiasing strategies, individuals could be able to see solutions they were not thinking about (or were aware of) since the heuristic processing was leading them to follow familiar patterns. However, it could also be argued that when people are detached from their subjective experience and intuition, they may end up following a more standardized, "cold" thinking process that could lead to less variability in their behavior. If this is true, we may conclude that, on some occasions, debiasing techniques may be detrimental when the goal is to look at possibilities that lie outside the realm of current knowledge. In other words, it could be that, under similar conditions, heuristic processing, with its shortcuts and intuitive associations, could lead different people to see different alternative worlds therefore increasing the likelihood to achieve disruptive changes

that open the way for things that were previously unthinkable.

To conclude, **heuristics** are part of people's way of making judgments, and it is hard to avoid them even after being trained about the errors they may provoke. They help simplify difficult and uncertain decisions in order to make them manageable and avoid freezing when it is not clear what should be done (e.g., when facing an hazard or a difficult economic decision). In the end the questions could be "would we be better off without **heuristics**?" Regardless from the approach used to study this subject, most researchers would agree that **heuristics** serve an important purpose and are instrumental to our adaptation to the environment. Right now, humans do have problems coping with the complexity and uncertainty that characterize some problems and decisions (Kahneman 2011). Therefore, in some specific contexts where the stakes are particularly high, we must do even more to help people understand how to improve the quality of their decisions. To this end, **technology** can prove especially useful and, to some extent, has already offered important solutions to overcome the limitations of human reasoning.

Definition

Hope and the possible are closely linked but the connection is complex. Feeling hopeful, hoping for something, or articulating hope reflects – or creates – a sense of the possible; that the hoped-for future, life, or phenomena is not out of reach, that it may happen. Hope is never certain, however, and does not equal possibility; it is related to anticipation and potential futures but is never granted. Rather hope is inherently disappointing. Studying hope and the possible is thus embedded in ambivalence and uncertainty.

In this entry, I discuss hope and the possible, with particular emphasis on anthropological and sociological studies. I start by outlining the concept of hope and its history in very brief terms and sketch the contours of current scholarship, followed by two sections on conceptualizing and searching for hope in times of crisis, respectively. I then turn to perspectives on governing hope and hopelessness and the relationship between societal and social hope(s), illustrated with examples from border control and West African high-risk migration and post-deportation life before I conclude.

A Long History and a Recent Revival

Exploring hope and the possible is a daunting exercise. Hope is used in everyday parlance, often casually, sometimes existentially. It has been conceptualized since (at least) the Greek antiquity, such as in the myth of Pandora, the

first human woman created by the gods who opened a jar of human evils that dispersed across the world while only hope remained inside the jar. In Christianity, hope is a central tenet, expressed in Paul's emphasis on faith, hope, and love while Aquinas identified hope as one of the theological virtues (Dalferth and Block 2016). While such Christian hope is a hope for salvation in the afterlife (Hage 2016), Immanuel Kant asked "what I may hope for," identifying three overall objects: one's own happiness, one's moral progress, and the moral improvement of mankind (Bloeser and Stahl 2017; McGeer 2004, pp. 100–101). Two centuries later, in the aftermath of the Second World War, Marxist philosopher Ernst Bloch articulated hope as "not-yet-become" and "not-yet-consciousness" in his magnum opus *The Principle of Hope* (1986 [1954]), emphasizing indeterminacy and anticipation (cf. Anderson and Fenton 2008; Thompson 2013).

Theorizing and contemplating hope has a long history, in other words. Nevertheless, the scholarship of hope has re-emerged and expanded dramatically within the last two decades. There is burgeoning literature within the social sciences, humanities, and social philosophy as well as in nursing, happiness economics, positive psychology studies, and indeed many other fields. Hope has been studied in, for instance, the history of home ownership in Hong Kong (Tsang 2021); as a technology of planning in Sheffield, England (Inch et al. 2020); post-disaster reconstruction in El Salvador (Sliwinski 2012, 2016); internally displaced persons in Georgia and asylum seekers in the Netherlands (Brun 2015, 2016; Ghorashi et al. 2018); literature analysis of *Middlemarch* (McGeer 2004); and the (short-lived) excitement about the Bosnian and Herzegovinian soccer team during the 2014 World Cup (Jansen 2016), to name just a few examples. In more quantitatively oriented work, hope indexes and hopelessness scales have been developed in nursing, psychiatry, and positive psychology to measure positive and negative expectations (Pleeging et al. 2021).

This proliferation of studies is also reflected in a range of review and state of the art articles that are currently emerging (see Cook and Cuervo 2019 on sociology; Jansen 2021 on anthropology;

Pleeging et al. 2021 for an interdisciplinary overview), handbook chapters (e.g., Kleist [forthcoming](#) on irregular migration), and encyclopedias and encyclopedia entries on hope and related phenomena, such as, indeed, “the possible.” In a recent review, Pleeging et al. (2021) identified seven overall themes and 41 subthemes in an analysis of 66 publications across traditional scholarly divides, while David Webb (2007) cited two studies from around the turn of the Millennium that counted 26 theories and 54 definitions of hope. Such exercises testify to the pertinence of the trope of hope today as well as the variety of how hope is perceived and employed.

Conceptualizing Hope

How, then, can we understand and define hope? This depends on the perspective and position taken. Within the broad field of anthropology, sociology, and other related disciplines, hope is generally approached as socially situated and contextual, shaped by – and engendering – the social imaginaries (Taylor 2004) that underpin our visions and perceptions of our lives and futures. Ernst Bloch’s *The principle of Hope* constitutes a continuing reference point, with its conceptualization of hope as an anticipatory consciousness toward the “not-yet-become” and as emerging conditions of the present (1986 [1954]). Bloch’s emphasis on “anticipation and the practical consequences of projections that simultaneously emerge in the present but point beyond it” has continued to shape scholarship on hope (Browne 2005 p. 68), even if Bloch’s explicit Marxist project is often ignored or downplayed (Jansen 2021).

Hope reflects a *sense* of the possible, in other words, but not necessarily what *is* or *will be* possible. After all, we only know the “not-yet-become” when it has become, so to speak. Elsewhere I have suggested an overall definition of hope as *anticipation of the future – or an elsewhere – that is characterized by potentiality but couched in uncertainty* (Kleist 2017b, [forthcoming](#)). We can be more precise, however, and distinguish between two overall modes of hoping: hoping for something specific and being hopeful,

what Webb (2007) has termed goal-oriented and open-ended hope. Anthropologist Stef Jansen makes a related distinction between the transitive and intransitive modalities of hope in the English language. The former concerns how “*hopes* for something or that something will occur” while the intransitive modality refers to how “the term ‘hope’ is used primarily to denote the affect of *hopefulness*” (2021, p. 2, emphasis in original; Jansen 2016). Julia Cook and Hernán Cuervo (2019) suggest the terms representational and nonrepresentational modes of hope, making a similar distinction between hoping for specific futures and affects and sensations of hope that do not revolve around a specific referent or object. They further emphasize that these modes of hope are not mutually exclusive or contradictory but “reflect multiple inherently connected modes, each of which is liable to shift into another” (2019, p. 1113). This point also problematizes discrete distinctions between hope as either inherently passive or active (*ibid.*, pp. 1006–1007; cf. Zigon 2009).

Whether hoping is perceived or experienced as an activity, a state, or an affect, the act of *hoping* takes place in the present. Hoping thus has a temporal dimension but not a fixed one. As Cook and Cuervo suggest, representational hope (or goal-oriented or hoping in its transitive form) is always future-oriented while nonrepresentational (or open-ended or hoping in its intransitive form) may be directed toward the present as well to cope with difficult circumstances. Such emphasis on hopefulness in the present is also central in Hirokazu Miyazaki’s works (Miyazaki 2004, 2006). Inspired by Bloch, Miyazaki calls for temporal re-orientation and the re-imagining of “the present from the perspective of the end” (2006, p. 157), where hope constitutes prospective momentums or is experienced as “sparks” (see also Haugen 2017; Pedersen 2012). Here hope (or rather hoping) becomes a practice or work.

Searching for Hope in Time of Crisis

Rather than settling on a specific theory or conceptualization of hope, I suggest it is more

productive to pay attention to the intensities, pluralities, and scales of hope and the modes of hopefulness (cf. Jansen 2021). I thereby approach hope as a relational and spatiotemporal phenomenon that is socially and contextually situated (cf. Webb 2007). This implies that hopes and hopefulness have histories and trajectories (Kleist and Jansen 2016) and that the conditions of possibility and political economy that engender or underpin them are important to consider. We may thus ask why there is a proliferation of interest in and invocation of hope from around the turn of the Millennium and ponder about its resonance in academic debates.

Considering this question, Jansen and I have suggested that this proliferation reflects a “widespread sense of crisis and a heightened sense of lack of political and ideological direction in this situation” (Kleist and Jansen 2016, p. 374) in which hope has resonance or is perceived as “a political and ethical virtue” (Anderson and Fenton 2008, p. 77). The shattered belief in a peaceful post-Cold War and, more generally, in modernist metanarratives of progress has distorted the social and political imaginaries that underpinned much of the twentieth-century political thought and development, we argued. Moreover, the militarized and securitized responses to these crises and their apparent lack of success and sustainability have added to a sense of lack of hope. One of the responses to this situation has been a surge of scholarship searching for and identifying hope in an extremely diverse range of topics and phenomena. Often the recognized or proclaimed hope is understood as inherently good and in accordance with the author’s own values and hopes (ibid.; Jansen 2021), being identified in (certain) resistance movements, activisms, and progressive or liberal politics (see, e.g., Solnit 2016).

Reflecting on the current moment 5 years after we wrote this analysis – after Brexit and the presidency of Donald Trump, and in light of the still ongoing Covid-19 Pandemic – it seems like a perhaps even more acute sense of crises and uncertainties prevails (cf. Scoones and Stirling 2020). Almost ironically, such a sense of intensified crisis may go hand in hand with a hardening of certainty, as reflected in the proliferation of fake news,

untruths, and growing polarizations (Back 2020; see also Solnit 2016). We may understand this as a situation of gloom or hopelessness. Yet, if we approach hope as a phenomenon that can be studied empirically, the ambiguities and even conflicts of specific hope(s) emerge. People hope for different lives and futures and these hopes may be contradicting each other or change over time. Both Barack Obama and Donald Trump rallied hope in their presidential election campaigns and policies, but these hopes revolved around very different visions of the hoped-for future and targeted different groups. Brexit offers hope to some and hopelessness to others. What is more, people may cling on to hopes whose realization appear impossible. Poignantly termed “cruel optimism” by Laurent Berlant, this refers to “a relation of attachment to compromised conditions of possibility” (Berlant 2011, p. 2). Just as instances of “the possible” are not valuable or desirable for all of us, neither are all instances and modes of hope.

Governing Hope and Hopelessness

An influential way of studying/approaching hope in the social sciences is in a political economy perspective, with attention to governance and the conditions of possibility underpinning hope. This prompts analysis of the production, distribution, and trajectories of (certain) hope(s) and modes of hopefulness or hoping; about whose hopes are supported or revived while others are deterred. Hope is “imbricated in different forms of power” (Anderson and Fenton 2008, p. 79) and it is distributed unequally to different groups, as anthropologist Ghassan Hage has argued (2003). Focusing on neoliberal Australia, he has suggested that states produce and distribute visions of the possible lives and futures for its population within society, generating differentiated societal hope, as he terms it, for different groups. Hope is governable and governed, in other words, and may thus have a distinct political dimension. The contentious topic of migration to Western countries constitutes a poignant example.

Since 2013, Australia has pursued an offshore processing policy where so-called spontaneous

asylum seekers will be transferred to offshore processing camps in Papua New Guinea and Nauru.¹ The camps have been widely criticized for human rights violations and cruelty (e.g., HRW 2021) and, for a while, an offshore processing policy was not considered politically possible (or dignified) to implement in European contexts. This has started to change, however. In 2020, the UK considered establishing an offshore processing camp at Ascension Island in the Atlantic Ocean but did not proceed (BBC 2021b). In 2021, Denmark passed legislation that allows offshoring asylum processing, followed by a memorandum of understanding with the government of Rwanda and an official government visit to the country to, it was speculated, discuss the possibilities of establishing an offshore processing camp there. A few months later, Denmark delivered 90 kilometers of concertina – a particular mutilating form of razor wire – to Lithuania to fortify 15 kilometers of its border and thereby hinder migrants and asylum seekers entering the EU from Belarus. The delivery was followed by a visit by the Danish Minister for Integration and Immigration to inspect the fence (Politiken 2021).

These developments show that the Australian, Danish, and indeed many other governments actively distribute hopelessness to migrants and asylum seekers considering or attempting to enter their borderlands or territories. Furthermore, they ensure that this message of hopelessness and its materialization through militarized surveillance, border fences that may literally carve up bodies, and policies or intentions of offshoring is widely medialized and communicated to potential asylum seekers as well as to citizens and voters. Such a policy spectacle (Kleist 2015) thus signals the political will to protect the nation's borders and promoting national interests for groups that perceive immigration as a threat. What is distributed hopelessness from one position may be perceived as an act of preserving hope from another

where tough-on-immigration policies generate societal hope.

My message here is not that an analysis of the governance of hope should be devoid of ethical and value-based considerations. We are always thinking, speaking, and writing from specific positions, and ethical and political standpoints and action may be called for (e.g., Solnit 2016; Back 2020; Nyabola 2021). In bell hook's words, "hopefulness empowers to continue our work for justice even as the forces of injustice may gain power for a time. To live by hope is to believe that it is worth taking the next step" (2003, pp. xiv–xv, cited in Back 2020, p. 5). Les Back (2020) and Solnit (2016) seek to inspire communality and agency through hopeful scholarship whose role is, in Back's formulation, "to portray and document and inventory of those moments of repair that suture damage, where hate gives way to love, convivial coexistence bridges divisions and inclusions" (2020, p. 18). Finally, Ghassan Hage calls for a politics of co-hoping and "modes of imagining one's own hope with the hope of others and not at their expense" (2016, p. 466). However, as he also notes, focusing solely on the distribution of hope "can blind us to the process of production" of inequality, including processes of extraction and exploitation (2016, p. 466).

Hope, then, may inspire and sustain engaged scholarship and practices that address inequalities and injustices. Indeed, I hope for that. My point here, however, is that we cannot assume that hope or hoping has an a priori liberating, emancipatory, or morally superior quality. In the introduction of a special section on the politics of hope, Marjo Lindroth and Heidi Sinevaara-Niskanen demonstrate this point forcefully when they argue that "hope and hopefulness are offered to those whom the world is unable or unwilling to offer anything else" (2019, p. 645). Such a position echoes Berlant's notion of cruel optimism, diagnosing hope in the service of exploitative political agendas, whether by design or through the inadvertent effects of political projects or programs. In line with Crapanzo's writing on the passive effects of hope (2003), Lindroth and Sinevaara-Niskanen suggest that the projected futures – the distributed hope – offered to groups of vulnerable people,

¹ The detention camp in Papua New Guinea will be closed from 2022 while the offshoring processing policy continues on Nauru (BBC 2021a).

such as victims of armed conflict or indigenous people reclaiming their land, maintains the status quo through placing the promise of change in the future, rather than today.

Social Hope in High-Risk Migration

Hope is thus a deeply ambivalent phenomenon, not least when invoked in and governed through politics. We should be careful not to conflate the distributed societal hope with the actual “uptake” of hope or modes of hoping. Political (and other) initiatives and projects do not necessarily pan out the way planned but often have inadvertent effects, whether in case of infrastructural projects (Appel et al. 2018), humanitarian reconstruction sites (Sliwinski 2016), or migration deterrence campaigns (Vammen *forthcoming*). The visions and intensities of inclusion, possibility, or entitlement – or the lack thereof – in the distributed societal hope may be embraced or seen as irrelevant. States are not the only distributors of hope in societies; there are a range of other institutions and actors that may constitute repositories and sources of hope (Cook and Cuervo 2019; Kleist 2017b; Turner 2015). It therefore makes sense to keep both societal and social hope in mind (Hage 2003) where the latter refers to “social imaginaries and collective visions of the good and meaningful life and future within particular societies and groups” (Kleist 2017b, p. 7). We may thus consider the societal hope distributed by the state as a subset of social hope, rather than necessarily the most important or dominant one. The importance of migration as an imagined pathway for a more dignified life and better future in West Africa is a case in point (Kleist and Thorsen 2017).

Studying migration implies attention to the spatial dimensions of hope beyond the nation-state (or beyond the current location of residence within the nation-state). Just as society is not necessarily delimited by the borders of the nation-state (Wimmer and Schiller 2002), neither is hope. Rather, social hope may be mapped onto specific locations or more blurry zones in different intensities and scales that reflect imaginaries of opportunities and principles of modes of

engagement – be it accumulation, pleasure, or security – that such places are perceived to offer (Mar 2005). As I have shown in the case of high-risk and precarious overland migration among, primarily, young men traveling overland from Ghana to Libya through the Sahara Desert (and sometimes onwards to Western countries across the Mediterranean Sea), there is a discrepancy between the visions of societal and collective social hopes that these groups receive and uphold (Kleist 2017c). Whereas societal hope revolves around notions of opportunities for upward social mobility in Ghana if you work hard and diligently, many young people find themselves in situations marked by unemployment and the lack of belief in a viable and dignified future in Ghana. Conversely migration constitutes a repository of social hope for would-be migrants, their families and communities. It should be emphasized, though, that migrants often articulate their hoped-for future as located in Ghana, rather than abroad, hoping for a transformation of their lives through migration. Furthermore, we should keep in mind that such social hope is not shared by everybody in Ghana (*ibid.*, Setrana 2021). It is not universal but comes in different variants and intensities; likewise, it may fade or grow stronger over time.

The ambivalence, uncertainty, and potential withering of hope is pertinent in another aspect of migration, that of deportation and other kinds of disrupted migration projects. The social hope invested in migration may turn to (temporary or long-term) despair and hopelessness for deportees and evacuees from civil war who return with no or insufficient resources (Kleist 2017a, c, 2020). Following social stigmatization, a similar or deteriorated economic situation as prior to migration, and inability to live up to ideals of respectable masculinity and adulthood, many deportees opt to re-migrate or are trapped in continued precariousness. Despite widespread knowledge of the hazards and risks of detainment and deportation in (what turns into) irregular migration, deportation tends to be individualized as an expression of personal “failure” or bad luck. The collective social hope invested in migration as a pathway to a better future is thereby maintained, through

downplaying the role of structural constraints, restrictive regimes of mobility and conflicts.

Conclusion

Considering hope in relation to the possible highlights issues of anticipation, potentiality, and uncertainty. As a central trope in European thought through centuries, even millennia, hope has been conceptualized and theorized in relation to different aspects of human existence, with a re-emergence of hope scholarship during the last two decades. While a plurality of themes, definitions, and accentuations can be identified, two overall modes of hoping stand out: that of hoping for something specific – *hope(s)* – versus the affect of being *hopeful* toward the future or as a way of coping with the presence. Understanding hope as a spatiotemporal phenomenon implies analysis of the wider political economies that ignite, sustain, or (seek to) extinguish particular hopes and hopefulness, whether in regard to the unfolding of specific hopes or their phenomenological or existential aspects (see, e.g., Lucht 2017). We may thus approach hope in many ways. Nevertheless, an understanding of hope as socially situated calls for analytical attention to the intensities, pluralities, scales, and trajectories of hope and hoping, and the conditions of possibility underpinning them.

Reflecting on the recent abundance of studies of hope, I suggest that this proliferation is embedded in a generalized sense of crisis and intensified uncertainties that prompt searches for hope (Kleist and Jansen 2016). We may further speculate that the so-called affective turn in the humanities and social sciences since the middle of the 1990s (Clough 2008) has stimulated more interest in hope and hopefulness as affective phenomena (cf. Anderson and Fenton 2008; Cook and Cuervo 2019). Indeed, one could argue that hope and uncertainty constitute critical affective dimensions in times of crises. Hope as affect does not preclude attention from the political economy of hope, however, and much current scholarship focuses on governing (through) hope, often inspired by Hage's work.

While hope has structural dimensions, it is not structurally determined, and hoping subjects may take up and embrace other visions of social hope – or their absence – than those inspired, produced, and distributed by the state. Migration toward Western countries illustrates this tension. On the one hand, states seek to send a message of hopelessness in migrating to their territories through restrictive migration regimes. On the other hand, migration continues to constitute a source of social hope in many societies, where hope for creating a more livable and dignified life and future is mapped onto locations or zones elsewhere. Whether such hope is realized is a completely different matter – in migration as in other aspects of life. Hope is fundamentally uncertain and ambivalent, it may inspire critical and engaged scholarship and political practices, just as it may postpone the redress of inequalities.

Abstract

The current dominant discourses on the benefits of a global market economy offer the illusion of a homogeneous world that is constantly moving towards progress. However, for thousands of rural communities, this process has meant a major impoverishment due to the expansion of agro-industry and extractive mine business, causing the destruction of

water sources and ecosystems, the forced displacement of peasants to urban centers, and the enormous loss to humanity of diverse cultures and knowledges.

The current Covid 19 pandemic evidences the enormous social and environmental debt with peasants, indigenous and Afrodescendant people, and other rural population who feed the world but are in a very vulnerable social, political, and economic situation, and therefore the importance of protecting and implementing their human rights.

All societies – globally, nationally, and locally – need to keep transforming unjust and exploitive relationships among people and with nature. Here we briefly present some discussions related with the need of special rights for peasant people from equality and equity perspectives, acknowledging the complexity and challenges that rural men, women, and children handle in their territories, inviting researchers from different disciplines, social leaders, and other practitioners, to join the implementation of their rights and keep dreaming, with the peasant movement around the world, the possible.

The Complex Interweaving of Equality and Equity Rights

Human rights theory and practice can be summarized as a commitment to respect, cherish, and treat all life with the utmost care, without any distinction. However, the complex interrelationship between universality versus diversity, equality versus equity rights is continuously on debate. The concept of equality involves the recognition that any person, regardless of race, sex, creed, or social status, should have the same rights, possibilities, and opportunities. “Equality” means that everyone should receive the

same or similar treatment. However, as the Ontario Human Rights Commission (2013) has indicated, the problem is that “formal equality” ignores historical and ongoing barriers, does not allow for special needs, and can even continue inequality for certain groups. Therefore, the need for the development and use of special programs as effective ways to achieve “substantive equality” by helping reduce discrimination, or addressing historical prejudice.

Facio and Morgan (2009) have called the attention to the restrictive formal way the concept of equality has been interpreted and applied in the history of women’s rights. For them, the concept of equality is androcentric, which is to say that men are the frame of reference and their experience is the norm, while the concept of equity allowed feminists to bring to the table the enormous differences not only between men and women but also the intersectionality of gender with ethnicity, economic class, geographic location, immigration status, sexual identity and orientation, age, abilities, and other such factors. Nevertheless, both authors argue, the term “equity” is a subjective term that can mean different things to different people. Human rights for women based only on equity would not have any practical worth because there will be thousands of justifications for limiting them for reasons of sex, ethnicity, age, ability, sexuality, etc. Instead, the term equality, as “substantive equality,” is measurable in that it can only be reached when there no longer exist any of the various forms of discrimination against women: “neither our differences nor our similarities should be reason for exploiting, discriminating against, oppressing, or in any other form dehumanizing us” (Facio and Morgan 2009: 23).

In the same order of ideas, Karima Bennouna, the United Nations special rapporteur in the field of cultural rights, examined the cultural rights approach to the universality of human rights, and the close interrelationship between universality and cultural diversity:

Universality is about human dignity, not about homogeneity. But we must also recognize the diversity of diversities, not only between, but within all human groups, and the fact that, among others, women, minorities, freethinkers and persons targeted because

of their sexual orientation or gender identity have also been wrongfully subject to hegemony and abuse within groups. (Bennouna 2018: 5)

Thus the complex interrelationship between universality and cultural diversity, equality, and equity has been under constant debate and scrutiny. It explains why different social movements around the planet have demanded to the United Nations to expand the human rights law from a dominant male, individualist, and liberal meaning to encompass specific standards for vulnerable groups such as women in 1979, children in 1989, persons with disabilities in 2006, indigenous people in 2007, and, more recently, peasants in 2018. However, a more equitable access does not necessarily mean more equal access. As Vivallo Urra (2013) have shown, the notion of equity, through compensatory operations, can perfectly coexist with the social, political, and economic processes responsible for the unequal access to resources that it tries to mitigate. Equity tries, therefore, to compensate, but does not guarantee human rights.

A Paradigm Shift: Human Rights from a Decolonial Perspective

A decolonial perspective contributes today on interpreting better the must-needed changes towards recognizing human rights across different cultures and groups of people (equality) without ignoring diversity (equity), not merely compensating but challenging the historical causes of social injustice and discrimination. As reviewed elsewhere (Sierra and Glăveanu 2019), the most recent United Nations Declarations of the Rights of Indigenous Peoples in 2007 and of Peasants and Other People Working in Rural Areas in 2018 draw on the resistance of racialized and oppressed groups against the dehumanization, exploitation, and genocide that have occurred during several centuries of colonization and that, in other guises, continues today. Both declarations challenge predatory and unsustainable economic models and are a call for a decolonial and eco-feminist agenda that allows the recreation of life under new terms, in balance with nature, based on social justice and

equity (Escobar 1998; Harding 2000; Mignolo and Walsh 2018).

The structure of the society and its worldview are still strongly influenced by the modern colonial project: a global hegemonic structure of power that has been in place since the European conquest, articulating race and labor, land and people, on the basis of material gains (Mignolo and Walsh 2018). As Escobar (1998) explains, over the last 50 years, concepts like “poverty,” “Third World,” or “underdevelopment” were coined to promote the First World’s capitalist model of development globally and extend costly credits to former colonized countries (neo-colonization). Indigenous people, rural Afrodescendants, and mestizo peasant populations in Latin America, for example, are those who have suffered predominantly the negative effects of such an oppressive system. This is evidenced by their persistent marginalization, the loss and neglect of their own languages, knowledge, and culture, their difficult access to good lands and water resources, and the frequent violation of their basic rights – to health, to education, to welfare, and protection.

The process of capitalist development, characterized by an economy of unlimited consumption, despite its multiple crises, reinvents ways to continue growing and demanding territories. This modernizing process has been extremely violent in territories where new areas of crops are grabbed by international markets, where minerals and fuel sources continue being extracted, and where new dams, roads, and ports are built to circulate goods. This is why the territories of indigenous and peasants’ communities continue to be the target of “development” projects and resource extraction, which ends up depleting them and displacing the women, men, and children who inhabit these territories, who have been preserving and cocreating them (Escobar 2014; Cárdenas 2015).

According to Harding (2000: 245–246), from an ecofeminist and decolonial critique, the conception of development as economic growth has generated several problems, among them, (1) the conceptualization of development and human progress only in terms of economic production, which made women and household work more susceptible to be exploited; as a result, rural women’s living conditions have worsened and

their workload has increased; (2) nature itself presents limits to economic growth, as the world does not have sufficient resources to sustain global consumerist growth, and (3) conceptualizing development in terms of increased economic productivity and consumption ignores and devalues other “goods” that women and other cultures prioritize such as ethical, political, aesthetic, and spiritual values.

Different peasant organizations and different experts have been insisting on the need for a paradigm shift against extractivism and extended monocultivation to, instead, strengthening family agriculture, local economies, community ties, and the reconstitution of the peasantry (Ploeg 2010; Hilmi 2013; Sourisseau 2014). “Peasants and rural workers and their families still account for nearly half the world’s population, yet nobody – or almost nobody – used to give a thought to their needs” (Hubert 2019: 92). Concepts and principles of alternative paradigms to development are needed: Ikerd, Gamble, and Cox (2014) suggest an economy of deep sustainability, when questioning the growing threats to ecological and social sustainability rooted in a neoclassical paradigm of economic development dominant today, which is inherently extractive and exploitative, that is, unsustainable.

Food Sovereignty, Agroecology, and Rural Women’s Rights

In the declaration of Nyéleni (2007), 500 representatives from more than 80 countries, of organizations of peasants/family farmers, artisanal fisherfolk, indigenous peoples, landless peoples, rural workers, migrants, pastoralists, forest communities, women, youth, consumers, and environmental and urban movements outlined food sovereignty as the right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems. “It puts the aspirations and needs of those who produce, distribute, and consume food at the heart of food systems and policies rather than the demands of markets and corporations. It ensures that the rights to use and manage lands,

territories, waters, seeds, livestock, and biodiversity are in the hands of those of us who produce food” (1).

Food sovereignty relates in a very pertinent way to agroecology, understood as the ecological management of natural common goods (air, water, land, and biodiversity), based on the application of local peasant and indigenous knowledge, to generate markets organized horizontally by the actors involved (Cuéllar Padilla and Sevilla Guzmán 2018). Unlike conventional and industrial agriculture, agroecology encourages greater knowledge about local ecosystems and sustainable agricultural techniques, which strengthens negotiation capacities and facilitates self-determination. According to Altieri and Toledo (2011), “after centuries of cultural and biological evolution, traditional farmers have developed and inherited complex agricultural systems, adapted to local conditions. These have helped to sustainably manage harsh environments and satisfy their subsistence needs, without depending on mechanization, chemical fertilizers, pesticides or other technologies of modern agricultural science” (cited by Delgado et al. 2013: 183). Agroecology as a science is a transformation alternative with great political potential, rooted in the power that people take when they recognize their own knowledge and historical contribution to the coevolution of agroecosystems and, at the same time, they give themselves the possibility of transforming their lives.

Timmermann and Felix (2015) highlight the role of agroecology for *contributive justice*, that is, the equitable distribution between meaningful work and tedious tasks. Conceiving the garden, the farm and the territory as an ecosystem requires paying close attention to the entire agricultural production process, which brings cognitive advantages, not only for food production. Agroecology makes the field work more interesting and encourages problem-solving, since farmers must develop skills and acquire valuable experiential knowledge on local ecosystems and agricultural techniques. This facilitates self-determination and makes farm work more attractive to a younger generation, an essential factor for safeguarding the continuity of family farms. By reconceptualizing and giving a

new value to work in the field, the principles of agroecology also contribute to the movement for food sovereignty and a greater well-being of rural families, particularly women.

Peasant women produce a large part of the world’s food and have been the guardians of traditional productive systems in which they have conserved germplasm and knowledge about them. However, these fundamental roles have not been recognized and promoted, and the overload of women is increasingly noticeable as they have to assume greater responsibilities in the productive dynamics, in addition to taking care of reproductive tasks, family health, the production of food for consumption, and to be the emotional support of their family nucleus. Likewise, they have been used in industrial agricultural systems as cheap wage labor. On the other hand, men are the ones who generally make decisions about the productive processes, even though the land belongs to women and they participate in the cultivation. To break initiatives to promote the strengthening of women as subjects of law are required that allow them to put themselves in a position of equality to work for a common future, in which their dreams, their potentialities, knowledge, and resources are also taken into account (Cárdenas 2015).

From eco-feminist educational experiences, Cárdenas and Zuluaga (2016) have shown how women, when they get to know their rights and knowledges, change their vision of themselves as mere agricultural helpers or laborers, engaged in insignificant jobs. Women learn to revalue the agricultural and food culture of their own territory, recognizing their contributions as producers of material goods (food, medicinal plants, and income) and symbolic goods (knowledge, innovation, and ability to create). They gain autonomy to define what interests them and defend their own options for associativity, the same ones that has led to these gains. By acquiring respect for their knowledge and work, women achieve important transformations in their families and communities. Agroecology is considered, then, of enormous impact for rural women due to its role in the reconstruction of the social fabric, environmental care, and food security of the family and local markets.

Peasants' Rights: An Historical Claim for Equally Substantial New Rights

Peasantry has a fundamental role in the right to food, in the conservation of biodiversity and in the mitigation of climate change through sustainable agriculture. However, because of their particular conditions, peasants suffer enormous vulnerabilities in a globalized world, which threatens peasant livelihoods, for example, through land grabbing resulting from the combined effect of the expansion of agribusiness, mining and real estate speculation. Based on this observation, the Declaration concludes that peasants require special recognition and protection by the States. (Uprimny 2018: 1)

In December 2018, the United Nations General Assembly adopted the Declaration on the Rights of Peasants and Other Rural Workers (UNDROP), at the initiative of La Via Campesina (LVC) movement, supported by the Centre Europe – Tiers Monde (CETIM), among other international organizations. The LVC union arose in 1993 out of earlier meetings that had pinpointed the similarities in peasants' conditions and difficulties in countries that seemed to have nothing in common but a related enemy: the World Trade Organization (WTO). Sharing analyses of their common experiences, the LVC peasants had developed a critical view of globalization and were aware of the dangers inherent in the worldwide liberalization of agriculture (Hubert 2019). After 25 years of discussion, this declaration was finally approved recognizing that the peasantry has particular living conditions because of its special link with the land and food production, and because of the development of particular forms of family and associative work.

As related by Hubert (2019), the declaration opens with a preamble presenting the concerns at the origin of the project, on how around the world, people living in rural areas are those most affected by hunger and poverty, along with those living in slums:

Today, rural workers do not earn enough and are under pressure from the cost of the inputs necessitated by the model of agriculture imposed on them. . . . Most peasant protests about their situation are met with repression and violence. To understand this scenario is to understand the urgent need to better protect the rights of peasants and

other persons working in rural areas. (The UNDROP, introduction. In Hubert 2019: 65–66)

The declaration has among its objectives: to protect the rights of peasants and improve the living conditions in rural areas, particularly of rural women; to strengthen food sovereignty, the fight against climate change, and the conservation of biodiversity; to encourage genuine agrarian reform and a better protection against land grabbing; for the right of peasants to save, use, exchange, and sell their seeds; and for remunerative prices for peasant production and the rights of agricultural workers, among others. Of the 28 articles covering the declaration rights, the leading organizations as La Via Campesina and CETIM highlight 7 because of their novelty and transformational potential: the right to land and other natural resources; the right to seeds; the right to a decent income and livelihood and to the means of production; the right to adequate food and to food sovereignty; the right to social security; the right to participate in decision-making; and, following from these rights, the general obligations on states (see Hubert 2019: 66–77).

A separate article of the declaration was devoted to the rights of peasant women and other rural women workers. As seen above, although women from rural contexts play a significant role in the economic survival of their families and in contributing to the rural and national economy, they are often denied tenure and ownership of land, equal access to land, productive resources, financial services, information, employment or social protection, and are often victims of violence and discrimination in a variety of forms and manifestations. The declaration stipulates, therefore, the need to change legislation that perpetuates discrimination against rural women. Their rights are one of the central pillars of the declaration (see Article 4 in Hubert 2019: 108–109).

The Multidimensional Nature of Rurality

In many different countries around the so-called Third World, the national educational systems are an imposed legacy of colonialist domination.

These educational systems, from preschool to university, are centralized, monocultural, and hierarchical, ignoring the learnings and contributions of indigenous, Afro-descendent, and mestizo peasant knowledge about the social and environmental complexity of their territories. Thus, the national educational systems contribute to the exclusion, marginalization, and invisibility of rural population. Lander (2000: 69), on his reflections on the geopolitics of hegemonic knowledge, sustains how the disciplinary structures of Latin American universities, “with their parceling of knowledge,” have become an obstacle to critically address questions about what and for whom of the knowledge that is taught and the research that is carried out. Current problems such as unlimited growth, wild capitalism, inequalities, human rights, militarism, and the risk to life on the planet are addressed in a fragmented way by different academic programs.

Haverkort and other authors (2013: 22), based on experiences with rural communities in Latin America, Asia and Africa, have expressed their concern about the injustice done to the diversity of cultures and local knowledge systems in the world if scientists, educators, and development practitioners limit their attention to imported knowledge and technologies of Eurocentric origin, which do not recognize the problems, challenges, and stakes of solidarity and self-consumption economies, which usually are described as premodern, retrograde, or primitive. Rural policies and education have been designed mainly from an economic and productive perspective, which peasants see merely as work force.

For Wallerstein (2001), the knowledge that is taught in universities ceases to be objective precisely because of the ignorance and denial of other knowledges. We cannot continue ignoring the political, economic, and power interests that have defined the evolution of modern sciences today, with adverse implications for the life of people and the planet (see also Fals Borda and Mora-Osejo 2004; Harding 1996; Haverkort et al. 2013; Nieto 2009).

If we consider rurality from a multi-dimensional view, we need to see the interrelating components of a territorial system. That is, taking

into account not only the economic and productive dimensions, but also the political, social, environmental, and cultural ones. The interaction of these dimension can, at a given time and circumstance, be as important as the main components. Based on Sepúlveda (2008), the *social and cultural dimension* refers to the spatial, gender, and population distribution in a territory and their relationships, which include aspects such as the satisfaction of basic needs, preservation of cultural heritage, and proper ecological practices. The *economic dimension* involves the interfaces of primary activities with those of processing and trade. It includes poverty eradication; access to goods and services; the creation of markets for sustainable activities; and the establishment and promotion of even markets. The *environmental dimension* relates to a balanced management of the ecosystems and natural resources. The *political dimension* has the democratic governance as a priority, looking at the interaction between hegemonic groups and other actors, as well as various types of political balances and negotiation processes.

The UNDROP contributes to a better understanding of the complexity and multiple dimensions of rural life. Different educational initiatives need to be created to ensure the knowledge of their rights by rural men, women, and children, and that they can strengthen their political participation and decision-making in all dimensions:

States shall formulate, in partnership with peasants and other people working in rural areas, public policies at the local, national, regional and international levels to advance and protect the right to adequate food, food security and food sovereignty and sustainable and equitable food systems. States shall establish mechanisms to ensure the coherence of their agricultural, economic, social, cultural and development policies with the realization of the rights contained in the present Declaration. (UNDROP, Article 15, 5).

Some Conclusions

With the adoption of the Declaration on the Rights of Peasants (UNDROP), the nations of the world face the challenge of seeking equity and equality, nondiscrimination and the right to development

for peasants and all rural workers and populations, to guarantee their right to participate in the management of natural resources and to enjoy in a fair and equitable manner the benefits of their development and conservation in their community, to provide land to work, as well as the right to access seeds to sow and distribute the products of their crops, and the right to income and decent livelihoods. This is a greater challenge for the educational systems (Hubert 2019).

Strengthening family and subsistence agriculture has been proposed as a key element in responding to global challenges such as climate change, food security, scarcity of fossil resources and employment, and emerging diseases. Self-consumption agriculture has persisted despite the invisibility with which it has been treated by development in the modernization process and by policies that have become a constraint and risk of its disappearance (Cárdenas 2015: 2).

Family and small-scale agriculture are inextricably linked to global food security. Family farming rescues traditional foods, contributing to a balanced diet, the protection of the world's agricultural biodiversity, and the sustainable use of natural resources. Family farming represents an opportunity to boost local economies, especially when combined with specific policies aimed at social protection and community well-being (Grisa and Sabourin 2019).

In agreement with Machado (2011), recognizing rural populations' rights imply reviewing not only the negative impacts of the so-called "green revolution" (abuse of agrochemicals, monocultures, and deforestation), but also understanding that rurality goes beyond the economic, productive, and competitive dimension of extractive economies. It is clear that the maintenance of present and future generations depends on the possibility that rural people can remain in their territory, strengthening their human and social capabilities, that they are not forced to emigrate due to poverty and violence, that there are environmental safe conditions, and an adequate standard of living for themselves and their families.

From an eco-centric paradigm, it is necessary to recognize the interconnection of reality and the fundamental unity of the universe and other more

responsible forms of social organization (Shea 1998). The recognition of the rights of peasants and other rural populations is part of another conception of life. Their implementation means transforming androcentric and anthropocentric oppressive paths of development and creating other possible ways of existing (re-existing, see Walsh 2015). It is our duty, as citizens of the world, to learn about indigenous people and peasants' rights to work towards their implementation in each sphere of human action.

Annex: The Colombian Case

Defeating the Vulnerability of Peasants' Rights: A Challenge for Universities

For us, territories are for life, that is, territories must be for people. For the neoliberal model, the territories are not for the people, that is, the territories are worth as soon as there is an economic interest there. . . . The territory for us is also spirituality, that is, the construction of that form of feelings, thoughts and relationships beyond the physical part. (Robert Daza, agrarian leader, in Quintana 2015: 1)

The territory is and forms part of our social and cultural experience and can never be considered as a commercial exchange property. For us, the owners and ancestral inhabitants, it is a space that welcomes the life of the communities in an integral manner, with its own peoples, cultures and social organizations, and that provides us with the natural resources for the reproduction of life and culture. (Ascoba-Asociación de Consejos Comunitarios y Organizaciones del Bajo. Atrato. Cited in Coronado 2009: 11–12)

Despite its relatively small size, Colombia is considered one of the world's ten "megadiverse" countries because of its varied ecosystems and cultural and linguistic diversity (Maffi 1998, 2005). About 33% of the Colombian population still lives in predominantly rural areas inhabited by indigenous people, rural Afrodescendants and peasant communities (small mestizo families dedicated to agriculture) (Machado 2011). The most recent agricultural census (DANE 2014) corroborated that Colombia is still a country with a high concentration of rural property. Land ownership in Colombia is far from being democratic: 69.9% have less than 5 hectares and occupy only 5% of

the census area, while lands of more than 500 hectares are in the hands of 0.4 of the owners and represent 41.1% of the 113 million hectares surveyed.

This concentration of land has been an endless source of conflict. The expansion of the agrarian frontier has generated deforestation, alarming poverty, and inequality (Mejía and Mojica 2015; OXFAM 2013; Misión Rural 2013). Peasants and other rural inhabitants continue having the least opportunities in society: 5% are in a condition of multidimensional poverty, 89% have no access to loans; illiteracy in rural areas of the country reaches 11.5% in those over 15 years of age (while the national percentage is 6.6%), 20% of children between 5 and 16 years of age have not attended any institution, and 73% of children under 5 years of age do not go to kindergarten (DANE 2014). As Cárdenas (2015) ascertained: in five decades of social and armed conflict, peasants, indigenous peoples, and rural Afrodescendants have lived through the pain of scattered horrors. The reality is overwhelming and shows Colombia as a characteristic example of capital accumulation through dispossession in the five last decades: 5.2 million peasants violently displaced from their regions and deprived of 8 million hectares, many of which were integrated into mining development as well as palm, sugarcane, and other monoculture projects.

This represents a social catastrophe as power continues to be in the hands of a few agents with broad territorial dominance: traditional landowners or hacienda owners, agricultural or mining entrepreneurs, drug traffickers in their search for social and political legitimacy, and the guerrillas as a state power. The peasant culture faces high risks of survival and environmental damage (Rojas Guerra 2012; Londoño 2015: 1–2); rural women were particularly affected (Cárdenas and Zuluaga 2016). Although there are historical achievements in the recognition of political, territorial, and cultural rights in favor of indigenous, Afrodescendants and peasant populations, achieved in the Political Constitution of 1991, the Law 70 of Black Communities of 1993, and

Law 160 of Rural Peasant Development of 1994, these rights continue on paper and rural populations continue to face the violation of their human rights, the destruction and loss of their territories by extensive cattle ranching, agriculture and mining, and the assassination of their leaders.

Unfortunately, to date the peasant person has not been recognized as a social subject by those who construct public policies in the country, generating a crisis for this social group, exacerbated by phenomena such as forced displacement, change in land use and concentration of ownership, inadequate use of productive resources and in general the conditions of poverty in the rural sector. (Misión Rural 2013: 3)

The economic role of the peasantry in food production, contribution to exports and foreign exchange generation has not been properly recognized, despite peasants' capacity to transfer surpluses to other sectors of the economy. The Misión Rural (2013) shows how small producers and family farmers are those who contribute to the country's food security and demonstrate not only economic efficiency when they have access to relatively acceptable production conditions but also the capacity to generate economic development and effective solutions to rural poverty.

Although Colombia was among the 54 abstentions for the Declaration of Peasants' Rights, the final vote by 193 member states in December 2018 lead to a new promising chapter in the struggle for the rights of peasants and other rural communities, guaranteeing their access to and control over land, peasant's seeds, water, and other natural resources.

Education in Rural Contexts Should Be Based on Socially Relevant Problems

According to our experience and discussions with rural participants from different Colombian contexts and projects (Calderón Serna 2015; Cárdenas 2015; Porras 2019; Sierra et al. 2010, 2016), education in rural contexts, from an equality and equity perspective, should serve to identify and address the different factors that render so vulnerable their rights. Vulnerability

aggravated by the absence of higher education programs relevant to the diverse social, cultural, and environmental rural contexts, which has led the new generations of rural youth to migrate to the cities in search of postsecondary studies and sources of employment to finally not return to their territories. Hence, for Jiménez (2017), addressing adequately the challenges of higher education in the rural setting should not become a priority but a national emergency, promoting the sense of belonging within rural society through a new rural educational policy, making the demands and rights of diverse rural population visible (Santos 2012), incorporating their life experiences, worldviews, and cultures; constructing with them other forms of learning, doing, and teaching (Arias 2017), and critically building knowledge dialogue with other views and perspectives.

To respond to this historical debt of advancing culturally pertinent higher education for diverse rural populations at Universidad de Antioquia, we developed a research project during 2012–2019 to design in collaboration an undergraduate program in *Pedagogy in Rurality and Peace*, to get the approval of the Ministry of Education and be formally offered in 2021. This implied the creation of alliances with peasants community organizations and NGOs that work with/from/and for rural communities and the Faculties of Education, Public Health, Agrarian Sciences, Social and Human Sciences, among others.

Different encounters, some formally organized through outreaches courses or diplomas, allowed us to explore better how the university should get closer to the rural communities and establish dialogue with diverse participants. With social leaders, men and women, young and elders, issues relevant to their contexts were identified, as well as objectives, themes, and guiding questions, reflecting on personal, family, community, and territorial life. A main issue is how participants' different personal interest and common topics should contribute to build or enhance the community life plans (CNA 2015), promoting participant's capacity for

action on different political spaces, not as passive subjects or mere recipients but as creators of their own reality.

All encounters with the diverse rural participants served as the basis for the collaborative curricula construction of the *Pedagogy in Rurality and Peace* program, which can be better described in the following Graphic 1.

The guiding questions help participating community leaders, women and men, to identify problems or situations to improve in their community, towards designing creative community proposals, which will configure the investigative work that each participant will develop. The creative community proposals configure the space of connection and tessitura of the discussions of the different training spaces, and at the same time the translation of them to their territory, from a collaborative and projection perspective.

The sustainability of rural communities and their ecosystems requires the strengthening of leadership capacities and creativity in their population, especially young people, in what we have seen as four content axes: territorial management, human rights, well-being of the communities, and pedagogies towards the construction of peace. These content axes are intertwined considering the challenge posed by an ecosystem perspective, that is, that the whole is meticulously articulated in all its levels and manifestations, and that each one of the parts can only be understood and explained in terms of the whole (Aristizábal 2001).

For a better understanding of the interrelation of the different content axes in the Pedagogy in Rurality and Peace Program, we use the metaphor of a tree, seen as a complex ecosystem itself (see Graphic 2 Tree of Knowledge).

Through the *Pedagogy in Rurality and Peace Program* by the University of Antioquia, we hope to contribute with discussions and reflections on the social construction of life and rights of peasant communities and other rural populations in Colombia, from decolonial paradigms and sociocultural perspectives of sustainability.

Technology, Organizations, and People (TOP) Model that supports integration of Technology, Organizations, and People during the whole life cycle of a system. HSI is inherently multi-agent, takes the system approach, and looks for the elicitation of emergent systemic properties through human-in-the-loop simulations (Virtual HCD). Human and machine are represented as systems defined by their structures and functions, which are characterized using the “context-resource orthogonality” framework. This encyclopedia entry provides HSI psychological and sociotechnical foundations, based on a nonlinear and self-organizing system perspective that departs from the traditional linear reductionist approach in psychology and engineering. This HSI epistemological endeavor addresses concepts such as separability, familiarity, emergence, tangibility, agonist-antagonist processes, symbiotic cognitive, and physical structures and functions.

Abstract

Human-systems integration (HSI) denotes a possible evolution of two disciplines, that are Human Factors and Ergonomics (HFE) and Human-Computer Interaction (HCI), that led to Human-Centered Design (HCD), more specifically within the field of Systems Engineering (SE). HSI pragmatically considers the

Introduction

The main objectives of this encyclopedia entry are (1) to improve our understanding of why psychologists and social scientists together with systems engineers and other stakeholders involved in the design of complex systems should be working in a participatory manner, (2) to provide salient elements of the emergent Human Systems Integration (HSI) field, and (3) to consider how new complex systems impact our working and everyday lives. But first, let us provide why HSI has become so important today, and opens the possibility of a new transdisciplinary endeavor in both science and engineering.

It is common to observe that technological systems are often integrated too late, leading to

both wrong or unexpected usages, and lack of resilience facing unexpected events. Resilience engineering has been studied (Hollnagel et al. 2006), but without providing solid fundamental engineering design solutions. A large amount of money is still spent to improve usages by developing appropriate user interfaces and operations procedures. This is the logical result of technology-centered Systems Engineering (SE) of the twentieth century. What did happen? Engineers had to design and develop machines mostly using mechanical engineering, making tangible things from tangible things (i.e., from pieces of metal that were assembled, screwed, and so on). During the last three decades of the twentieth century, electronics and software were massively incorporated into mechanical machines to improve their functionalities and usability. Automation (automatic control) and Human-Computer Interaction (HCI) were the main disciplines that were used to this end. This move could be summarized as the **hardware-to-software shift**.

Let's take an example. During the 1970s, car engines could be mechanically maintained more or less easily by car owners. Today, once a failure occurs, car owners let car maintenance professionals provide a diagnostic using a software-based system that provides meaningful information, such as the price it will cost to fully repair failure's cause. This shift increases system's availability by minimizing time it will take to repair the car. System's components have become standardized, easily changeable, and disposable.

Since the beginning of the twenty-first century, almost all technological systems are designed on computers. First concepts are presented on PowerPoint slides. Then, more sophisticated models are produced using appropriate Computer-Aided Design (CAD) tools. These models are subsequently used into simulations, which are with human(s) in the loop. More specifically, Human-In-The-Loop Simulation (HITLS) provides means for discovering potential emerging behaviors and properties that cannot be anticipated without observing activity of the various human and machine agents. By enabling incremental discovery of emergent behaviors and properties (Boy 2013), HITLS is a key resource for

Human-Centered Design (HCD), which cannot be done without an agile development approach (Schwaber 1997, 2004; Sutherland 2014). In fact, HITLS makes HSI possible and effective. This is great news! However, since such virtual HCD relies on the use of virtual prototypes, now often called digital twins, tangibility is at stake and needs to be considered seriously. Indeed, a virtual prototype of an aircraft is not a real aircraft! The virtual prototype has to be transformed into a physical prototype. This move could be summarized as the **software-to-hardware shift**.

Let's take an example. Aircraft wings are digitally designed using CAD and fluid dynamics software, providing requirements for the development of wings, which can be 3D printed to produce physical wings. Most importantly today, tangibility of emerging Artificial Intelligence (AI) algorithms (also called data science) used in design and operations of complex systems must be studied in depth. The concept of digital twin is crucial in HITLS. Many instances of digital twins are currently available, more specifically in the form of aircraft simulator (Fig. 1).

Let's emphasize the need for HSI, where a system can be both a human and/or a machine. It provides epistemological foundations for the psychology of HSI, articulated around concepts such as separability, familiarity, emergence, tangibility, agonist-antagonist processes, symbiotic cognitive and physical structures and functions, and most importantly a nonlinear and self-organizing system perspective that departs from the traditional linear reductionist approach in both psychology and engineering. Tangibility assessment still requires combining creativity and experience, as well as complexity, flexibility, stability, maturity, and sustainability metrics.

Human System Integration: A Historical Approach

It would be difficult to make sense of HSI without defining the distinction between **task** and **activity**. A task is what is prescribed to be done. An activity is what is effectively done once the task is executed. Task analysis has been extensively used to

Human-Systems Integration, Fig. 1 Example of a tangible combat aircraft simulator

H

support the design of user interfaces (Kirwan and Ainsworth 1992; Mori et al. 2002; Diaper and Stanton 2004). However, usability studies have shown that activity observation and subsequent analysis are crucial to improve interaction design (Kaptelinin and Nardi 2006) and ergonomics (Leplat 2008). For a long time, the main problem was that activity was only observable on existing systems whether currently used systems prior to novel design or once a new system was fully developed. On the one hand, activity analysis on existing systems prior to starting engineering design usually forces conservatism and continuity; disruptive innovation can be considered as dangerous. On the other hand, activity analysis once a new system is fully developed is likely to show design flaws that will or will not be possible to fix in depth from a systemic point of view; only cosmetic patches can be brought at the user interface level. This has been done for a long time.

Historically speaking (Fig. 2), the field of Human Factors and Ergonomics (HFE) was born after World War II. Ergonomists are mainly psychologists and physiologists. During the early 1980s when micro-computers started to be adopted by a large public and more specifically text processing was starting to become current practice, ergonomists got interested in the way people interacted with computers. Human-Computer Interaction (HCI) was born, introducing new kinds of investigations where computer scientists

had to deal with human factors in computing systems (Card et al. 1983). HCI specialists took the lead on the design of Graphical User Interfaces (GUIs). HCI contributed to the development of a large set of task analysis methods, limited however to computing systems and not necessarily to multi-physical complex systems, such as aircrafts, air traffic control systems, and nuclear power plants, where observed activity is generally different from related prescribed tasks, typically provided in the form of operations procedures. Related user interfaces, whether they are called cockpits or control rooms, involve deeper considerations than what generic desktop GUIs usually bring. Unfortunately, many user interfaces tend to hide engineering design flaws, and unfortunately adapt people to developed systems, creating situation awareness problems in critical situations.

Since the beginning of the twenty-first century, SE started to become aware of the importance of human factors in engineering design. HSI of sociotechnical systems was born as a combination of HCD and SE. More specifically, HSI is intrinsically model-based, and concurrently considers Technology, Organizations and People (TOP) during the whole life cycle of a system (Fig. 3). This is the reason why the modeling framework shifted from single agent to multi-agent.

HSI requires a more formal definition of what a “system” is about. But before providing a definition, it is important to state that HSI opens the way

Human-Systems Integration,

Fig. 2 Evolution of human-centered technology approaches

it all, but by selecting relevant parts that make sense to us. Relevance is about meaning. We can talk about meaningful reality, and not about objectively sensed reality.

What Does the Term “System” Mean?

A system is a **declarative representation** of either a natural or an artificial entity. Natural entities can be human beings (e.g., human beings are open nonlinear systems in Klochko’s sense), organs of a human being (e.g., physicians talk about neurological system or cardiovascular system), plants and animals or organizations of them (e.g., the reproduction system of flowers by pollination associating bees; flocks of birds). An artificial entity can be an abstraction (e.g., an idea, a law, a method), an object (e.g., a chair), or a machine (e.g., a car, a washing machine) that was built by a human being to facilitate and support the execution of specific tasks. A system has at least a structure and a function (Fig. 4). It can be either cognitive (or conceptual), physical, or both (Boy 2017). Today, machines have cognitive functions (e.g., the cruise control function on a car enables the car to keep a set speed) and cognitive structures (e.g., interconnectivity within systems of subsystems such as an industrial company). Note that a human can include a machine (e.g., a human may have a pacemaker machine), and a machine can include a human (e.g., an aircraft includes pilots and passengers).

Human-Systems Integration, Fig. 3 The TOP model for Human-Centered Design

to a new multi-agent approach, in contrast with the single-agent approach provided by human information processing models (Newell and Simon 1971; Rasmussen 1986), to psychosociology, introducing an alternative to traditional linear approaches considering cognition and socio-cognition as sequential information processing. HSI considers from the outset that the systems are open, nonlinear, and self-organized in the sense of the theories proposed by Taleb on the one hand and Klochko on the other (Taleb 2007; Klochko 2007). Taleb proposed this new definition of systems from an extrinsic point of view (i.e., our environment can be considered as an open nonlinear and self-organized system). Klochko proposed an intrinsic point of view (i.e., our cognition can be considered as an open nonlinear and self-organized system). Klochko’s proposal follows stages of child’s development proposed by Piaget (1936), and the selective property of our mind proposed by Vygotsky (Vygotsky et al. 1993). Our brain is able to process gigantic amount of information, not by processing

Human-Systems Integration, Fig. 4 The cognitive-physical structure-function representation of a system

In addition, the conventional single-agent definition of a system function as something that transforms an input into an output should be extended to a multi-agent perspective. In the teleological multi-agent sense, a system function is defined by three attributes:

- A role
- A context of validity
- A set of possible and necessary resources

At this point, it should be noted that the concept of “system” commonly used in systems engineering is very similar to the concept of “agent” in artificial intelligence and cognitive science. For example, a postman is an agent of an agency that is commonly called “The Post”. The post can be represented by system of systems, where the postman is a system. A typical postman’s function can still be defined as having a (prescribed) task of “delivering letters” (i.e., function input). His/her activity (i.e., function output) may not always reflect such a prescribed task because the context may change, either his/her capacity may intrinsically change (e.g., the postman is tired or sick), or environmental factors may extrinsically change (e.g., heavy rain or excessive traffic).

Context of validity of postman’s role (i.e., delivering letters) can be defined by a time context (e.g., from 8:00 am to noon, and from 2:00 pm to 5:00 pm) and a space context (e.g., the neighborhood where he/she has to deliver letters). Context can be normal (i.e., the same job every day) or

abnormal (e.g., some other postmen are not available and the postman in duty needs to expand his/her time and/or space context). Postman’s resources can be physical (e.g., a bag and a bicycle) or cognitive (e.g., a pattern-matching cognitive function that enables him/her to put each letter in the right mailbox, matching the name of the street, the number of the house and the name of the addressee). At this point, it becomes clear that a function is a function of functions (e.g., “delivering letters” is a function of another function, the “pattern-matching” function). More generically, function’s resources are systems, which can be either physical, cognitive, or both. This representation is very convenient for function allocation in a SoS (i.e., among systems [or structures] in a network of systems).

Various Types of Situations for Context Management

The term “situation” is commonly used to denote something that happens, such as an event, a state of affairs of someone, a location or a process at a particular time, or a context that specifies a set of persistent conditions. A situation can be a generic pattern, or an episodic set of conditions. Summarizing, we will consider that a situation is defined by a set of states, in the common sense of control theory. More formally, a situation S may refer to a dynamic set of states (i.e., a situation varies in time), $S(t) = \{s_i(t); i=1,n\}$, including multiple

Human-Systems Integration, Fig. 5 Various interconnected human-centered meanings of the situation concept

derivatives, in the mathematical sense, such as velocity and acceleration (i.e., a situation is not only a static description, but also an evolution).

Following what Mica Endsley already described in her situation awareness model, the perceived situation also needs to be understood at a conscious level (Endsley 1995a, b, 1998; Endsley and Garland 2000; Boy 2015). The concept of situation has several interrelated facets (Fig. 5): the “real situation” is characterized by an infinite number of highly interconnected states; the “available situation” is characterized by a set of states available to a human observer through external sensors; the “perceived situation” is a subset of states of the “available situation,” directed, augmented, and/or transformed by what is being expected (i.e., the “expected situation”) and the long-term memory of the agent (i.e., the “background situation”); the “expected situation” supports event-driven behavior (i.e., what we anticipate); the “meaningful situation” is a subset of the “perceived situation” augmented by the “desired situation” (i.e., what we want to do) and the background situation (i.e., directed by experience and habits); we can talk about an interpretation process at this point; the “desired” situation expresses a goal-driven behavior (e.g., what we want to get from what are doing in the current situation); the “projected situation” can then be considered as a subset of the meaningful situation

augmented by the background situation (e.g., experience and habits).

Systems as Resources: The Multi-Agent Paradigm Shift

For a long time, engineering schools taught linear algebra as a major mathematical package for future engineers. Very little attention has been brought to nonlinear models and complexity science. Consequently, engineers tend to think linearly. In addition, human and social sciences tend to adopt most popular mathematical models for data analysis, mostly in statistics (e.g., linear regression). It is not surprising that both worlds (i.e., engineering and human factors) have difficulties when nonlinearities occur in the course of industrial or life-critical operations (Boy 2021). The Taleb’s Black Swan metaphor is interesting to consider here because it encapsulates the concept of human antifragility that involves signals for homeostatic processes that fight to keep the overall system safe and working (Taleb 2007¹). In other words, in everyday practice, moving from linear to nonlinear consists in moving from

¹A second edition, published in 2010, provided a new section on robustness and fragility; ISBN 978-081297381.

Human-Systems Integration, Fig. 6 Procedures, automation and problem solving leading to the allocation of human and machine functions (Boy 2020)

procedure following, to cooperation with machine automation to problem solving (Fig. 6).

Many complex systems and complex situations cannot be reduced to simple linear systems or situations, we need to get familiar with them in order to understand them and adapt to them. The opposite concept of complexity is not only simplicity, it is also familiarity. For example, when you move from one location to another for living, you are likely to find the new location very complex to navigate in it, but after a few months, you become familiar with it, locating the bakery next to the shoemaker, and so on. The more familiar you become with the new location, the more you find it simple to navigate in it. What really happens relies on the network of shops, streets, roads and houses and their interrelations (i.e., their systemic structures and functions). When you have become familiar with nodes and links of this network, everything becomes so simple! Therefore, instead of avoiding complexity by reducing it to linear models, it is crucial to learn about this complexity (i.e., become familiar with it).

In many situations (i.e., normal, abnormal, and emergency), human operators of life-critical systems typically follow procedures and/or use machine automation. However, outside of such procedures and automation definition contexts,

human operators have to directly solve problems. In these cases, they need to have enough autonomy to handle current situations correctly.

What do we mean by autonomy? Being autonomous requires knowledge, experience and sometimes boldness. When these requirements are not present, human operators have to get external assistance. This is where the multi-agent approach enters into play. An autonomous system is necessarily a multi-agent system, because it is equipped with the necessary agents that are capable of following appropriate procedures, using automated tools, and solving problems at hands, either intrinsically (e.g., a mountaineer who learned and trained enough to have necessary knowledge and skills to climb a difficult peak) or extrinsically (e.g., a team of aerospace engineers and astronauts that has all necessary knowledge and skills to solve a problem in a spacecraft such as in Apollo 13 successful accident). An excellent illustration is the experience of Apollo 11, when Neil Armstrong landed on the Moon (Mindell 2008). An intrinsic multi-agent system is not equivalent to a single-agent system because it is equipped with a “team” of sub-systems working together (e.g., functions working not only in sequence as a classical information processor, but also in parallel, cooperatively and/or competitively). An extrinsic

multi-agent system is what we usually call a multi-agent system for short.

The distinction between automation to autonomy deserves to be better understood. Automation is about defining, developing, and using procedures defined in a specific context. Automation deals with a close, linearized and rigid world. It is usually thought as a single-agent system. Autonomy is about incremental learning of experience in multiple contexts and handling expected as well as unexpected situations using intrinsic knowledge and skills and dedicated extrinsic support. Autonomy deals with an open, nonlinear, and flexible world. Consequently, it is about trust, collaboration, and self-organization. It is typically thought as a multi-agent system.

A first solution is to consider models the systemic interaction models (Boy 2020): supervision; mediation; and cooperation. Considering these three systemic interaction models, combined with procedure following, cooperation with automation and problem solving (Fig. 6) contributes to a useful multi-dimensional multi-agent model that should also consider that agents can be working together toward a same goal or the opposite. We are facing an epistemological question of defining how multi-agent systems work. A specific answer to this issue was provided in system science by Bernard-Weil who proposed the agonistic-antagonistic paradigm that combines cooperation and competition of two groups of agents (Bernard-Weil 2003). Bernard-Weil studied the dynamics of agonistic-antagonistic bio-medical networks to better understand emerging phenomena, and types of control when unbalances between the two groups of agents occur. Further work should be devoted to this fundamental question. In the meantime, let us concentrate on a method that enables the elicitation of knowledge useful for giving life to such multi-agent systems.

Associating Procedural and Declarative Knowledge: The PRODEC Method

The association of the situational framework defined in section “[Various Types of Situations for Context Management](#)” together with the

system declarative representation provided in section “[Systems as Resources: The Multi-Agent Paradigm Shift](#)” leads to what is denoted “context-resource orthogonality” (i.e., the articulation of procedural and declarative knowledge). Procedural knowledge is about timeline of events and actions (e.g., stories, episodes, scripts, procedural scenarios), and describes meaningful situations. Declarative knowledge is about multi-agent organizational structure-function models and describes resources as systems. Procedural and declarative knowledge respectively denotes what is functionally and structurally possible.

Cognitive psychology and computer science cross-fertilized each other for a long time. Indeed, procedural knowledge and its distinction with declarative (or conceptual) knowledge has been developed in several fields related to cognition such as educational science (McCormick 1997) and development psychology (Schneider et al. 2011), including mathematics education (Star 2005; Hiebert and Lefevre 1986; Carpenter 1986), user modeling (Corbett and Anderson 1994), and an experimental psychology (Willingham et al. 1989; Lewicki et al. 1987; Richard 1983).

The theater metaphor helps figuring out what the PRODEC method is about (Boy et al. 2020). First, a writer produces an essay that tells a story, available in a procedural manner. Then, a director selects, in a declarative manner, actors who have to read the essay and learn their roles and scripts procedurally and coordinates them. PRODEC has been designed to be used in HCD to benefit from both operations experience (i.e., human operators will be asked to provide their salient operations stories) and definition of objects and agents involved in the targeted human-machine system to be designed (i.e., the design team will provide prototypes at various progressive levels of maturity). PRODEC consists in using the following procedure:

1. Elicit and review all tasks involved in the achievement of various goals
2. Describe them as procedural scenarios
3. Elicit cognitive (and physical) functions in the form of role (associated to tasks and goals), context, and associated resources (declarative scenarios)

4. Describe and refine elicited resources in terms of structures and functions (using the formalism presented in Fig. 4)
5. Iterate until a satisfactory solution is found

Procedural knowledge is elicited from subject matter experts in the form of chronological scenarios, together with system-of-systems performance criteria for the assessment of accuracy, impact, and probability of collaboration and trust, for example. System performance relies on the articulation of three factors encapsulated within the *AUTOS Pyramid*² (Boy 2011).

Tangibilization deals with system's physical and figurative (or cognitive) tangibility assessments (i.e., the fact that we can grasp a system physically and figuratively). Figurative tangibility is about meaningfulness. Domain ontology, or system ontology, can be divided into functional ontology and structural ontology.

Conclusion

This entry of the Palgrave Encyclopedia of the Possible proposes a fundamental approach to human-systems integration (HSI) from a psychology and social sciences perspective, associated to useful concepts, methods, and tools for its development. HSI deliberately takes a long-term perspective, where possible futures are anticipated and tested from the very beginning of the life cycle of a sociotechnical system. HSI contrasts with the traditional engineering approach that necessarily considers causal prediction of short-term futures. HSI is both a process and a product, which should take place as early as possible during the design process and evolve during the overall life cycle of the product. Being able to observe activity at design time is a brand-new capability in engineering design, because modeling and virtual prototyping means are now available and realistic enough to support human-in-the-loop simulations.

Human-centered design combined with agile systems-of-systems engineering approaches,

effectively supports HSI. Indeed, technology, organizations, and people must be considered concurrently during the whole life cycle of a system in which functions can be incrementally allocated to more appropriate agents with respect to appropriate principles and criteria. This means that HSI is no longer a matter of adapting people to machines by crafting, often too late, user interfaces and operations procedures, but an integrated approach based on the system-of-systems concept that integrates people and machines into articulated sociotechnical systems. In fact, HSI theory is far from being fully developed, and requires more formal investigations and heuristic experimentations. More specifically, HSI dictates that improving autonomous complex systems requires improving autonomy for all stakeholders, including people and machines.

HSI requires more investigations based on complexity science and system science, where concepts and issues, such as emergence, separability, and complexity familiarity, should be further explored. Finally, HSI developed using digital twins should be based on strong tangibility principles, scenarios, and assessment criteria, properly defined along five directions: complexity, maturity, flexibility, stability, and sustainability. Number and content of these dimensions will be probably extended with respect to ongoing engineering design, research, and innovation developments.

Playfulness · Wittiness · Incongruity-
resolution · Creativity · Irony

Definition

Humor comprises, in its broadest definition, *everything* related to the funny. This includes how humor is perceived, appreciated, and produced by individuals, but it also includes humorous stimuli (texts, cartoons, jokes, situations) and their properties. The concept of incongruity is postulated as a central element of humor in many theories and models; as such, humor is inherently related to the possible. The present chapter first defines humor and gives a brief overview on humor theories. Then, the family of incongruity-resolution theories of humor and the wittiness model of humor are described, as they are particularly relevant for understanding the relationship of humor and the possible. Next, the relevance of individual differences in humor and aspects of humor development are discussed. Then, empirical findings on humor and humor interventions are presented briefly. The final section explores the links between humor and the possible from five perspectives: playfulness, creativity, (in)tolerance of ambiguity, as-if behaviors/irony, and changing perspectives. Overall, the possible is a central aspect of humor, and humor can be seen as a playground for the possible and the impossible.

Definition and Theories of Humor

Humor is a term that had different connotations throughout history and that is still used with different meanings nowadays (Martin and Ford 2018; Ruch 2008; Ruch et al. 2018). The most prevalent interpretation of the term humor in current research is as an umbrella term that entails all funny or comic phenomena (see Roeckelein 2002). Thus, humor in this broad sense comprises whether people recognize humor (e.g., if they understand that an utterance is meant ironically rather than literally), how they comprehend humor (e.g., interpret a sexual innuendo in an innocent or in a sexual way), to what extent they appreciate humor (e.g., how funny, aversive, or boring they find a joke), which humor they produce, and how they communicate it (e.g., telling long and complicated anecdotes, imitating accents, parodying other people, criticizing problems in a funny way).

When looking at humor “theories,” one finds different theoretical accounts dating back to ancient philosophers such as Plato and Aristotle. What is most striking about these theories and ideas is their heterogeneity with respect to the aspects they are explaining and the fact that there is no theory that explains “humor” in its totality. In an early review, Keith-Spiegel (1972) differentiated between eight families of humor theories (note that for most accounts, different variants exist that also evolved over time, and thus we rather speak about families of theories). Adapting her categorization, we differentiate between seven families of theories. All of these families of theories focus on certain aspects of humor: Some focus on the properties of humorous stimuli, and others focus on aspects of humor processing or responses to humor. A few authors also tried to integrate some of these families of theories (e.g., Suls 1977).

1. Biological accounts and theories that assume that humor/laughter evolved as a means of nonverbal communication or to serve social functions, such as signaling safety and vocal grooming (i.e., producing pleasing sounds). These theories focus on the functions of humor and laughter over the course of

- phylogenetic development (i.e., evolutionary changes).
2. Superiority theories assume that laughter arises from the perception of being superior to others, and thus laughing at others serves as an enhancement of one's own ego. These theories focus on explaining emotional and motivational aspects of laughing at others (for an overview, see Ferguson and Ford 2008).
 3. Incongruity theories focus on explaining the cognitive mechanisms of humor processing or the structural properties of humorous stimuli. Incongruity denotes something that is unexpected and/or "does not fit," which is also labeled a violation or incongruence of what is expected or "normal." These theories focus on what makes a stimulus funny in terms of cognitive and structural "ingredients" and the stages of cognitive processing necessary in order to understand humor; for example, they would describe how a joke "works" and how a person would perceive, interpret, and react to the joke. Importantly, incongruity has been recognized as a necessary, but not sufficient ingredient in humorous stimuli (for more extensive explanations, see Forabosco 2008).
 4. Configural theories are a variant of incongruity theories that give more weight into the *insight* into how elements, configurations, or thought patterns, which are seemingly unrelated, fit together to become the source of amusement (i.e., the Gestalt, the holistic perception of the configuration). These theories thus focus on the "bigger picture" that is conveyed by jokes, cartoons, and other humor stimuli.
 5. Surprise, ambivalence, release/relief, and violation-based theoretical accounts describe the importance of the respective elements for the experience of humor and emotional responses to it. These theories also focus on humor processing and the properties of humorous stimuli, but postulate specific important "ingredients." For example, surprise might be a necessary, but not a sufficient, element for experiencing humor (e.g., surprise about the punch line).
 6. Psychoanalytic theories focus on the explanation of how humor, wit, and the comic can serve to regulate psychic energy and make

explicit reference to psychoanalytic theory and thinking in general. For example, Freud (1905, 1928) described humor as a mature defense mechanism that should help to deal with negative experiences by allowing an expression of inappropriate drives in an appropriate (humorous, playful) way. Freud also dissected jokes and explained them with various cognitive (e.g., exaggeration, hyperbole) and affective mechanisms (e.g., sexual and aggressive contents).

7. Linguistic theories mostly deal with the properties of humorous stimuli, such as the *Semantic Theory of Humor* (Raskin 1985) or the *General Theory of Verbal Humor* (Attardo and Raskin 1991). These theories try to comprehensively explain the ingredients and properties of verbal humor, including the targets (i.e., who is the "butt" of the joke) and the logical mechanisms (i.e., how the joke "works").

Incongruity Theories of Humor, Humor Processing, and Humor Production

Particularly important to the understanding of the possible is the family of theories often referred to as "incongruity-resolution" theories (for an overview, see Ritchie 2018). They emphasize cognitive processes underlying humor, including structural properties of funny stimuli or the ways in which individuals process such stimuli. Although these theories differ in their terminology, their core premises are very similar: Humor is postulated to contain at least one incongruity that is perceived in Step 1. This incongruity usually results from a "mismatch" between the joke setup and the punch line, as the latter is unexpected. Step 2 consists of a full or partial resolution of this incongruity (e.g., Suls 1983; Wyer and Collins 1992). It is assumed that people go back to the joke setup and reinterpret it to make it fit to the punch line, for example, by changing their interpretation of a specific word or expression. If this mismatch cannot be fully resolved and there is still something left over that does not make sense, then we speak of a partial resolution.

What distinguishes humor processing from other types of problem-solving is the playful frame of mind (also labeled a “non-bona fide mode”; see Raskin 1985) in which these stimuli are perceived; that is, the humor stimuli are non-consequential and thus constitute a safe, benign, and non-threatening environment in which these incongruities can be explored (Suls 1983; Warren and McGraw 2016). Depending on the two steps of humor comprehension and the frame of mind in which the stimuli are processed, humor can then be more or less appreciated in Step 3. While humor appreciation is linked to prior comprehension, the two are still separate processes (see Chan et al. 2012, 2013; Ruch and Hehl 2007). For instance, one can understand a joke (i.e., successful humor comprehension) but not find it funny (i.e., lack of appreciation). Conversely one might not get the punch line of a cartoon (lack of comprehension), but one still finds something else about it that is perceived as funny (e.g., the drawing style or the facial expressions of the protagonists in the cartoon).

In comparison to humor processing (i.e., comprehension and appreciation), the production of humor has been less well studied (for an overview, see Ruch and Heintz 2019). Humor production targets the generation of something funny, ranging from spontaneous utterances in daily conversations (e.g., jokes, puns) to professional performances (e.g., comedians, improv comedy). None of the abovementioned families of humor theories explicitly target humor production, and only one model attempted to explain the different steps underlying humor production: Feingold and Mazzella’s (1993) multidimensional model of wittiness. The model comprises three stages: One first needs to be motivated to produce humor (humor motivation), then one needs to be able to generate humor (humor cognition), and finally this humor response needs to be uttered (humor communication). Feingold and Mazzella (1993) propose that different processes underlie these three stages, with humor cognition being linked to cognitive abilities (e.g., verbal intelligence) and humor motivation and communication being more closely related to personality and temperament (e.g., sociability) and the situation (e.g.,

appropriateness of humor in the situation, audience).

Individual Differences and Developmental Aspects

While the above outlined theories and models seem to propose a rather uniform scheme in which humor is processed and produced, it is important to note that considerable individual differences exist, both between persons and within a person. For example, people differ with respect to the humor they appreciate: Some people have a preference for simpler, easier to solve forms of humor (incongruity-resolution), others have a preference for more abstract and sophisticated humor that contains incongruities that cannot be resolved or that can only be partially solved (nonsense), and yet others have a preference for humor that contains a specific content such as sex or aggression (Heintz 2019; Ruch 1992; Ruch and Hehl 2007). Furthermore, people differ in the humor they produce, ranging from benevolent to mocking and from simple to sophisticated forms of humor (Ruch et al. 2018).

Additionally, humor processing and production change throughout the life span. Cognitive development theories (for overviews, see Bergen 2018; Hoicka and Akhtar 2012) postulate that humor co-develops with increasing knowledge, reasoning, and linguistic abilities. With the increasing cognitive capabilities of children, the humor they appreciate and produce becomes more complex as well. Once a cognitive schema is developed, the child can recognize occurring incongruities (starting from actions to words and concepts). In addition to these ontogenetic aspects (i.e., development within a species), the phylogenetic development of humor (i.e., evolutionary perspective across species) is relevant as well. As summarized by McGhee (2018), humor is not only understood, appreciated, and produced by humans but also by chimpanzees and gorillas; for instance, after learning sign language, great apes intentionally mislabeled objects to their caretakers, followed by a play display.

Research on Humor and Humor Interventions

The different families of incongruity-resolution theories received ample empirical support from different disciplines in psychology, including social psychology (e.g., Warren and McGraw 2016), cognitive psychology (e.g., Suls 1983; Wyer and Collins 1992), and neuropsychology (e.g., Chan et al. 2012, 2013). This research has shown that most humor is indeed dependent on incongruities and a (partial) resolution, which indicates that the circumstances are safe. Additionally, Chan et al. (2012, 2013) found that the three stages of humor processing (perceiving, resolving, and appreciating the incongruity) are routed in different areas of the brain, supporting that they rely on different neuropsychological processes. Similarly, Feingold and Mazzella (1993) showed that their different steps in humor production were related to different outcomes; that is, humor recognition and production were more strongly related to ability than humor communication, and the reverse pattern was found for relationships with personality and temperament (e.g., sociability).

Importantly, these studies mostly relied on dedicated verbal (jokes) and visual (cartoons, pictures) humor stimuli. Thus, the external validity (i.e., transfer to spontaneous humor in everyday life; see Craik et al. 1996) and boundary conditions (e.g., what is required to be a “safe” situation) of these theories still remain to be tested. Furthermore, no theories have yet covered the full humor process, from perception, comprehension, and appreciation to motivation, cognition, and communication. Importantly, these theories do not yet account fully for individual differences; for instance, different people likely require different levels of resolution to appreciate humor (see Ruch 1992), and the kinds of incongruities (i.e., appropriate incongruities, Oring 2003; possible and impossible incongruities, Rothbart and Pien 1977) that are preferred might differ between people and within the life span. Furthermore, the same humorous stimulus can be differently interpreted depending on the situation in which it is presented and depending on the current mood

(i.e., humor states); for instance, one would expect the same joke to be more appreciated in a relaxed social setting with friends than in a more serious or demanding situation (e.g., an exam or a business meeting). Such an integrative account of both general processes and individual differences is required to fully understand how “humor works.” This would also enable to understand how the different steps and stages mutually influence one another and whether their interplay differs between people (e.g., degree of comprehension needed to appreciate humor) and situations (e.g., mood, situation characteristics, situation norms).

Although it is often assumed that some people just have a sense of humor and others do not, research has shown that humor can be trained (for an overview, see Ruch and Hofmann 2017). A variety of trainings have been developed and tested in the literature, comprising individual or group-based, personal or online, and standardized or ad hoc trainings. The best-evaluated program is Paul McGhee’s 8-week 7 Humor Habits Program (2010; for an overview, see Ruch and McGhee 2014), which can enhance one’s sense of humor, playfulness, and cheerfulness and lower one’s seriousness. In addition to increasing humor, these interventions can also enhance psychological well-being (see Hofmann and Ruch 2019).

Humor and the Possible

Humor is connected with the (im-)possible regarding several different aspects: playfulness and playing with ideas (see also the chapter on Play, this volume), creativity (see also the chapter on Creativity, this volume), (in)tolerance of ambiguity, as-if behaviors and irony (see also the chapter on As-if thinking and Irony, this volume), and changing perspectives. It should be noted that the individual standards of what is interpreted as humor and as possible and impossible differ depending on the situation (e.g., mood, cultural and societal norms, audience), individual characteristics (e.g., abilities, temperament, personality, sense of humor, disorders), and the developmental stage (e.g., cognitive and emotional development

of children). We thus focus on the general overlap of humor and the possible in these concepts, while acknowledging that the standards of what is possible and what is funny differs within and between persons and may change over time.

To be able to perceive humor, individuals need to be in a certain frame of mind (or state). It is conducive to humor if individuals are in a relatively relaxed, stress-free frame of mind and motivational state (or alternatively, they need to be willing to switch into such a state of mind). Individuals are more likely to detect and process humor in a playful frame of mind (rather than a serious frame of mind; see McGhee 1979) or if they are in a paratelic (i.e., activity-oriented, playful) motivational state (as opposed to a telic motivational state; Apter 2001). Humor was claimed to involve a non-bona fide rather than bona fide mode of communication (see the work of Raskin 1985). This playful and non-serious frame of mind allows us to play: to play with language, ideas, and concepts. For example, being in a playful mood helps to understand and appreciate punch lines, as not only the logical consequence of a joke setup is expected or favored, but instead different explanations that could (partially) explain a punch line are sought for. Similarly, a playful mood could help to create more and better punch lines by exploring different ways a joke can yield an unexpected, yet somewhat plausible resolution. Playfulness has been shown to be strongly related, albeit not synonymous with humor (see Proyer 2018 for an overview). This differentiates humorous communication from most other forms of communications we use, which is based on serious, goal-oriented, rational thinking and speaking.

Creativity is usually defined as creating novel and useful solutions (also labeled “divergent thinking” as compared to convergent thinking, which is traditionally considered “intelligence”). Humor, especially spontaneous witty humor creation, is often conceptualized as an aspect of creativity (for an overview, see Ruch and Heintz 2019). Creating humor without time constraints (e.g., writing punch lines to a captionless cartoon) is an inherently creative task, especially when participants create novel punch lines or combine

existing punch lines into new ones on the spot (as in improv comedy, see the chapter in this volume). In other words, spontaneous humor production essentially entails testing different, potentially suitable possibilities (quantity or fluency aspects) and eventually selecting the best and funniest possibility (quality aspect).

(In-)tolerance of ambiguity (i.e., liking or disliking stimuli, behaviors, and experiences that have more than one meaning or interpretation) is a personality trait that has already been related to humor in the 1980s (for an overview, see Ruch 1992). The direction of the relationship depends on the humor structure: Preferences for incongruity-resolution humor (i.e., punch lines that can be fully resolved) were related to intolerance of ambiguity, while preferences for nonsense humor (i.e., punch lines that cannot be fully resolved) were related to tolerance of ambiguity. Tolerance of ambiguity accommodates different possibilities, while its opposite spectrum favors a single, logical possibility. At the same time, nonsense humor incorporates the idea of impossibilities; that is, the punch lines do not have to make perfect sense, but they can entail fantastic, illogical, and unrealistic incongruities (e.g., talking animals, alive objects) as well as multiple incongruities that increase the ambiguity of the stimuli. These elements are not entailed in incongruity-resolution humor, reducing the range of possibilities entailed in such humorous stimuli.

As-if behaviors and irony, which are related to the histrionic self-representation style (Renner et al. 2008), occur if a person does something that is different from what they actually mean. In contrast to lying, the person expects the audience to understand that the behavior or utterance is not meant to be taken literally, but that the observed meaning differs from the implied or symbolic meaning. For example, a child could pretend that a banana is a phone by holding it close to their ear and speaking into it, or a speaker could say that it is a lovely weather when it is actually pouring rain outside. While as-if behaviors and irony are inherently related to the possible, they are not inherently funny or humorous, though they can serve as vehicles to create amusement for oneself and the audience.

A final overlap between humor and the possible is the change of perspective that humor can encourage. A humorous worldview is an attitude that is speculated to be at the core of humor (Freud 1928; Martin and Lefcourt 1983; Ruch and Heintz 2016). This humorous world view entails a broadened perspective and thus a distance from everyday experiences, thereby allowing to consider different possibilities underlying a situation. This can help to solve problems, to alleviate stressors, and to achieve a more nuanced and light-hearted perception of the world.

Conclusion

This chapter showed where humor overlaps with the possible, based on theories of humor processing (incongruity-resolution theories), wittiness, and cognitive development and on constructs that capture elements of both humor and the possible (i.e., playfulness, creativity, tolerance of ambiguity, as-if behaviors/irony, and changing perspectives). While we highlighted the similarities between humor and the possible, especially from a cognitive perspective, it should also be mentioned that humor has unique social and affective elements, such as its entertaining (e.g., comedians, improv comedy), socializing (e.g., in-group cohesion by shared humor and laughter), corrective (e.g., satire, parody), and mocking (e.g., bullying, ridiculing) qualities.

Beyond this general introduction, the interested reader may also consider the relationship of humor and the possible with respect to verbal humor and its possible or impossible translation. This important topic to linguists and experts of translation studies has received growing interest over the past three decades. Here, it shows that translating elements of the possible from one language to another pose many difficulties and may also be impossible in some case – and funny utterances in one language may not be translatable at all or turn out unfunny in other language contexts (see Attardo 2017; Maitland 2017; for an overview, see Hofmann and Rodden 2019).

Hypothesis

Martin W. Bauer

Department of Psychological and Behavioural Science, London School of Economics and Political Science, London, UK

Keywords

Supposition · Rhetoric · Dialectic · Public reasoning · Theory of perception · Model of the mind · Heuristic · Scientific method · Monologicality

Definition

The word “hypothesis” is of ancient Greek origin and composed of two parts: “hypo” for “under,” and “thesis” for “to put there”; in Latin, this translated “to suppose” or “supposition”; made up of “sub” [under] and “positum” [put there]. It refers to something that we put there, maybe to start with, maybe to stay with us as an installation. Hence in modern English we say “*let us hypothesize, suppose,*” or “*let us put it that . . . ,*” and then we start the argument by developing implications and reaching conclusions. The term “hypothesis” marks a space of possibilities in several ways. Firstly, it is the uncertain starting point from which firmer conclusions might be drawn. Public reasoning examines how, from uncertain hypotheses, neither true nor false, we can nevertheless reach useful conclusions. Secondly, the hypothesis is the end point of a logical process of firming up on reality through scientific enquiry. Scientific methodology makes hypothesis testing the gold standard of enquiry. Thirdly, hypothesis is a point of transition that calibrates perception and social interaction. Psychological science turns hypothesis testing into a model of the mind. And finally, hypotheses might be part of a monological ritual of reasoning that distracts from reaching a common understanding about the world and its utopian possibilities.

In the “*Man Without Qualities*,” the writer Robert Musil puts it into the title of Chapter 4

“*Where there is a sense of reality, there must be a sense of possibility.*” It seems that we cannot have reality without acknowledging other possibilities, without the imagination that things can be entirely different but for some reasons are not. Reality is framed by possibility, and it is imagination that opens this space of contingency. But we must then ask immediately, how do possibilities arise in the first place?

The word “hypothesis” is of ancient Greek origin and composed of two parts: “hypo” for “under,” and “thesis” for “to put there”; in Latin, this translated “to suppose” or “supposition”; made up of “sub” [under] and “positum” [put there]. It refers to something that we put there, maybe to start with, maybe to stay with us as an installation. Hence in modern English we say *let us hypothesize, suppose, or “let us put it that . . . ,”* and then we start the argument by developing implications and reaching conclusions.

One can trace a term with Ngram Viewer, which, based on millions of English books, visualizes how keywords fall in and out of fashion. Figure 1 shows the relative salience of “hypothesis” and “supposition” since 1600. Both terms were in higher use between 1700 and 1850 and then fell out of favor; later after 1950, only the “hypothesis” regained currency and stabilized in the 1980s at a level of higher usage.

In this entry, the notion of “hypothesis” denotes a space of possibilities in three different contexts without any claim to being comprehensive.

- (a) Public reasoning examines how, from uncertain hypotheses, neither true nor false, we can nevertheless reach useful conclusions.
- (b) Scientific methodology makes hypothesis testing the gold standard of enquiry.
- (c) Finally, psychological science turns hypothesis testing into a model of the mind.

Hypothesis in Public Reasoning

An ancient classification of reasoning is based on whether we start with premises that are true, or

Hypothesis, Fig. 1 Ngram Viewer for keywords “hypothesis” and “supposition” as references in English books between 1600 and 2019 (accessed 15 Dec 2021)

from premises that are uncertain, or even untrue, but nevertheless lead to useful conclusions. Aristotle identifies the latter with dialectics and rhetoric, two formats of communication which come naturally so that “*ordinary people do this either at random, or through practice and from acquired habit*” (Barnes 1984, Rhetoric, 2152).

Pure syllogism comes to true conclusions from premises that are already true, famously, “All men are mortal” [Major, rule], “Socrates is a man” [Minor, case], “therefore Socrates is mortal” [Conclusion, result]. Such demonstrations are examples of deductive logic. Without any doubt on neither the Major nor the Minor, the conclusion is incontestable. From truth only truth can follow; the opposite is however not the case. **Hypothesis marks an uncertain starting point.** In order that from less than true, a truth can follow, some further considerations need to come into place. Dialectic and rhetoric seek to clarify in the case of everyday reasoning such conditions of hypothetical reasoning.

Dialectic is suited to the context of one person arguing with another, where the stronger argument shall prevail; we might recognize here the rationality that tends to prevail in a seminar discussion or a debate. Here interlocutors start with sentences such as “*let us suppose that . . .*,” “*let us assume that . . .*,” “*let it, for the sake of argument, be agreed that . . .*,” or “*let the hypothesis be made that . . .*” (Rescher 1964, p. 3). What is supposed is not an established fact, not further investigated; to the contrary the claim remains doubtful, possibly true or false [God exists?]; it can be wrong in common belief [John Lennon is alive]; and it can even be definitely false [Napoleon has won at Waterloo]. Such types of uncertainty are the basis of hypothetical reasoning (Rescher 1964, 4ff). Under the heading of “topics,” Aristotle listed suppositions which can be safely made in general or in particular contexts and which carry credibility without further examination, i.e., “*those opinions are reputable which are accepted by everyone or by the majority or by the wise . . . or by the most notable and reputable of them*” (Barnes 1984, p. 167). Important in everyday life, with contingency planning, we learn to remain prepared on how to shift to

plan B if conditions are changing. In thought-experiments, we trace the consequences of knowingly false assumptions. We might even play games with our imagination by extrapolating impossible assumptions in “what if” stories as in science fiction, while politicians avoid hypothetical questions “what if the PM resigns next week . . . ?.” Any answer to this question would reveal a position and give hostage to fortune; better wait until the situation arises. And modern public opinion research compares what are the common places of different strata of people; these sets of feasible arguments define at present social representations (Bauer and Gaskell 2008) or a historical mentality (Lloyd 1990, 135ff).

In rhetoric, by contrast, the hypothesis is unspoken, it is buried in the tacit communality that ground all rhetoric between speaker and listener/reader. Rhetoric takes place as civic discourse; speakers are addressing a larger audience in public. It is famously defined by Aristotle as “*observing in any given case the available means of persuasion*” thereby considering feasible arguments (logos), credibility of the speaker (ethos), and audience appeal (pathos; Barnes, “Rhetoric” 2155). We recognize here the rationality of the public sphere. The rhetorical argument is called “enthymeme,” a truncated way of arguing by saying not as much as to bore people, but nevertheless saying as much as to persuade; we must consider people who “*cannot take in at a glance a complicated argument, or follow long chains of reasoning*” . . . (ibidem, p. 2157) “*common places to be embodied in them*” and “*thus we must not carry its reasoning too far back, or the length of our argument will cause obscurity; nor must we put all the steps that lead to our argument, nor shall we waste words in saying what is manifest*” [ibidem, p. 2224]. Hence, somebody might seek to move people by claiming that *smoking is dangerous to your health [minor], therefore stop smoking! [conclusion]*. Whoever wants to move people to give up smoking needs to make sure that they work on safe ground that *people want to live a healthy life and live longer*. This is indeed the unspoken hypothesis [major, rule] which underpins the enthymeme urging you to give up smoking. The

common place “living a healthy life” is implicit; it is tacitly shared and mutually assumed in the discourse [I know that you know that I know . . .]. The enthymeme builds on the hypothesis; no need to enquire any further, for the sake of brevity to sway opinions. Only the analysis of the rhetorical situation brings the implicit hypothesis to light as the common ground on which the speaker is successfully working. What is unconscious might be made conscious; however, stating the “bleedingly obvious” could be irritating. Rather than challenging an explicit assumption, it is better to be left unexamined in order not to complicate an already pressing situation and a convenient framework for action.

While dialectic is concerned with epistemic truths, seeking to establish a plausible truth from uncertain, though explicit hypotheses, rhetoric has a practical remit of establishing what can be done under uncertain conditions and time pressures, whether somebody can be blamed for a state of affairs, or whether a person deserves our respect; and to achieve this, the hypothesis remains implicit. Modern rhetoric extends to the marketplace: advertising moves us to buy stuff in order to live a happier life of satisfied consumers.

Hypothesis in Scientific Methodology

The term “hypothesis” is part of the core language game of science: theory, model, measurement, data, research question, and hypothesis (Glass and Hall 2008). Often hypothesis is confused with model or theory, such as “biological evolution as a hypothesis” or “big bang as a hypothesis.” It is more useful to distinguish hypothesis derived from theory or model, which can be tested on data. A model represents the theory that gives rise to hypotheses (Frigg 2010). The hypothesis then becomes the research question reformulated in data terms. All this struggle testifies to historical anxiety of science vis-à-vis the imagination as a human faculty (Daston 2005); it needs to be domesticated like a wild animal to extract utility.

Scientists working experimentally are taught to frame their designs on Nature with a hypothesis about the effect of a controlled intervention; for

example, the effect of a drug to treat an illness, or a training protocol to increase performance, can be tested statistically for significance. The experimental design of treatment, controls, and outcome variables allows *ceteris paribus* to attribute causal efficiency from the intervention X to the outcome variable Y. The existence of an effect Y and the strength of the relationship X-Y are subject to prediction, i.e., the hypothesis based on a causal mechanism $X \rightarrow Y$. This type of “causality hunting” leads in the social sciences to a ritual of hypothesis testing; this frantic chase to reject null hypotheses of ill-defined effects has entered a “replication crisis”; social and psychological effects are not replicable as drug trials are (Scheel et al. 2020).

Harre (1985, 62ff) distinguishes a fictionalist from a realist account of **hypothesis as knowledge**. For the fictionalist, theories and models are entirely imaginary entities that allow to generate useful predictions to be tested on data. When different models equally fit the data, the choice between models is done on endogenous criteria such as coherence, beauty, or simplicity. For the fictionalist, planets do not exist beyond words [nominalists]; these entities allow us to formulate a theory of moving light points in the sky under an observatory. This kind of reasoning can proceed from manifestly false propositions and deduce a conclusion that is empirically true, for example: all humans are rational (F), and all rational creatures behave like this (F, Bayesian updating); therefore, rational humans behave like this (T) (see Harre 1985, p. 84).

For the realist, however, theoretical entities are more than “names” in the universe; they can be demonstrated by the gesture of pointing. The sun is not just the center of a planetary model; it can be pointed at in the sky; the same might be true for “behaving rationally,” it can be pointed out. The realist adheres to three principles: a) some theoretical terms refer to hypothetical entities, b) some hypothetical entities are candidates for existence, and c) some candidates for existence exit (Harre 1985, p. 99). This seems to be best illustrated by the microbial theory of bacteria and viruses. Bacteria and viruses infect and kill cellular organisms; they are not just convenient fictions predictive of

infectious complications and excess deaths during a pandemic.

Some of the entities referred in a theory or a model are hidden from sight, not (yet) directly observable, as **hypothetical constructs**. Famously, for a neo-behaviorist psychologist, minding is only a hypothetical construct producing a “cognitive map,” which explains how an animal successfully moves in a maze after reinforced trials. Such constructs mediate between observables, the antecedent conditions, and the performance. Statistical models help by deriving probabilistically latent traits or latent classes of objects, so-called latent variable models. Given antecedents and performances, we infer a hypothetical level of “intelligence.”

The **hypothetico-deductive method** is formally specifying hypotheses to reach explicit clarity and objective generality from a theory. This method was used by Johannes Kepler who had lots of observational data about moving planets, and he played in his mind with geometrical curves, where beginning and ends coincide. By thus playing with geometry, a deductive system of axioms, he came to consider an ellipsis rather than a circle, and he then derived predictions for elliptical orbits and low and behold the data fit the model and simplified things at the top of it. Henceforth, astronomers model planetary orbits in the geometry of ellipses rather than circles (Harre 1985, p37ff). Based on the authority of astronomy, the psychology imitated this way of reasoning for theories of learning (Foppa 1965, 33ff), heuristics and problem-solving (Groner 1978; Suppes 1983), and behavior (Lewin 1931, 1936). By contrast, behaviorists like Skinner utterly rejected hypothetical entities like “cognition” or “consciousness” as irrelevant and focused on observables with reinforcing effects on behavior. Intermittent reinforcement is most effective; the occasional “likes” on Twitter or Facebook will make us superstitious and crave for more.

A famous intervention in these matters states that hypothetical constructs are necessary to break superstitions, but prone to self-fulfilling verification; they can never be verified, only falsified. For Popper (1972, p. 37), this demarcates what is and what is not “science.” Science must generate propositions

that can be falsified. According to the doctrine of **falsificationism**, what does not fall under this criterion is unscientific. Hypotheses can arise from any form of imaginary, belief, or doxa; there are no rules or laws for their generation, but they need to be testable and tested. For this “critical realism,” Yoga, astrology, homeopathy, herbalism, psychoanalysis, conspiracy theories, or Marxism might contribute to knowledge provided they produce testable predictions in their area of observation; otherwise, they are nothing but pseudo-scientific superstitions. Feyerabend (1981, p. 194) traces this idea to John S Mill, who in the nineteenth century advocated that the procedures of science are “*not to praise what is good, but to eliminate what is bad, or comparatively inferior,*” thus making a link to ideas of evolutionary selection and survival of the fittest in the test. However, not every falsification challenges a hypothesis; counter evidence must accumulate before it breaks the imaginary of the scientific community (Peters 2013).

Another understanding of hypotheses arises from the philosophical program of pragmatism. Pierce celebrates a third type of inference, the **abduction** (Psillos 2011). This is different from induction – moving from the specific to the general rule – and from deduction – moving from the general rule to the specific case. Abduction is also called “retroductive inference,” or “inference to the most plausible explanation.” Abduction specifies a methodical way of inferring a hypothetical explanation which, however, requires further investigations. As such it specifies the thinking by which Sherlock Holmes solves his cases (Eco and Sebeok 1988).

- [Rule, strong Major]: *dogs do not bark at their master.*
- [Result]: *there was a theft; the dog did not bark in the night.*
- [Case; weak Minor; hypothetical explanation]: *the master must be the thief.*

Sherlock Holmes solved the case of the “curious incident in the night” as follows: the facts are “*there was a theft in the night and a dog that did not bark.*” Then comes the simultaneous intuition from rule and result: “*ah . . . hey . . . watch-dogs*

do not bark at their masters [rule, strong major], as there was no barking at night [result], the thief must be the master [case, potential explanation]. Let us confront the master; if he confesses, we have the decisive evidence." This intuition is facilitated by switching slightly from "dogs do not bark" to "watch-dogs do not bark." Given what is known, an abduction is consistent with that evidence, but we need to exclude other persons the dog might not bark at. In rhetoric, this move of suggesting a plausible conclusion comes by the name of apagogé: an indirect proof that an explanation is well consistent with the facts by dismissing rival explanations. The facts are a start, the **hypothesis is but transitory** in the middle of the action.

Scheler (1960 [1925], 460ff), on knowledge in modern society, commented on this historical shift of meaning of "hypothesis" from a potentially real entity to a purely fictional construct. Originally, hypotheses referred to constructs which explain existing facts and predict new facts. Such ideas include "viruses" or "atoms" and "aether" or "phlogiston." The former two were confirmed by future research, the latter become obsolete. In psychology, the debate about consciousness as "hypotheses" continues; some see it in the light of the Hicks-Boson, about to be verified at CERN; others make the analogy to "phlogiston," about to be obsolete. However, a hypothesis is still hoped to refer to a real entity that one day can be pointed at, though not yet.

Under the influence of modern pragmatism, the meaning of "hypothesis" shifted to that of a **convenient model** whose only function is to guide effective action. The model of various instantiations (visual, verbal, material, statistical; Frigg 2010) is locally adjusted in response to the resistance of reality. The model assumptions are arbitrary as much as they have simplicity and lead to useful implications; e.g., the earth is flat; how far can we go? or humans are entirely rational; what is the level of inflation going to be? Any real experience that goes beyond verifiable sensations is a hypothesis, including the dark side of the Moon, which we will never see from the Earth.

This leads Max Scheler to distinguish ironically between the idealist, the pragmatic, and the

"wise." The idealists are fixated on the "true reality" against appearances; they thus tend to ignore or dismiss the resistance of the world. The pragmatists are lost and disoriented in random worlds and busying themselves with fixing locally operative models; for them the world is a local construction that is temporarily useful. For the "wise" (i.e., phenomenologists like Scheler confessed to be), who sense the need for firmer orientation in a random world and for whom pragmatism is too short term, both the images and the world are eminently real and neither is to be taken lightly, and the moon really has a dark side.

Hypothesis in Psychological Science: The Once "New Look"

Psychology classically deals with thinking and subjective experience related to social interaction and the body; cognition is dually embodied, socially situated, and organically incarnated. When Brentano clarified the trichotomy of minding into intentional acts of representation, judgment, and feeling [cognition, evaluation, conation], a hypothesis seems to fall into the limbo between representation, the intentional minding of an object, and a judgment about its existence; a **hypothesis remains suspended** without any conviction whether the object exists or not. In addition, we might feel attracted or repelled by this object (Brentano 2015 [1874], p. 295). The unicorn comes to mind, it is intentionally inexistent, but widely liked.

Behaviorists dismissed all this as drivel and focused their research dogmatically on how habits form from effects. Classically, an innate response of salivation in the sight of food gets associated to the sound of a bell; henceforth, the dog salivates when the bells ring. In the operant mode, any behavior, however superstitious, can become frequent if reinforced; thus, behavior becomes fit for circus performances, and social media.

Neo-Behaviorism, imitating the physical sciences, postulated hypothetical constructs for learning theories; it was argued that hungry animals form "expectations" and "cognitive maps" of where to find food. To these laws of effect,

Gestalt psychologist juxtaposed the spontaneous learning by insights. Human and other animals do not always follow a random path of trial-and-error littered with reinforcements. Much learning occurs in sudden bursts of “insight.” After some trying without progress and calm examination of the situation, Samson the chimp suddenly grabs the stick and steps on the table to reach the banana dangling from the ceiling. Stick and table, lying about, suddenly acquired functional value for his problem: a banana out of reach. Samson displayed mentality and spontaneous behavior, motivated but not shaped by consequences (Koehler 1925).

What is being learned? The cognitivists’ answer includes not only habitual behavior, but **mental structures** as well: stimulus expectation, motor image, causal attribution, determining tendency, disposition, attitude, or a conditional expectancy mind-set of the kind *if-X then do A, then you will reach Y*. This mind-set is not accessible by introspective experience; it is only a hypothetical construct, a condition on the side of learners which modify the selection and processing of information (Foppa 1965, p. 186). This leads to the once “new look” on perception as a process going beyond the information given: perceptual cues are ordered into meaningful patterns, cues are recognized in the light of a schema that affords perceptual readiness (Bruner 1974, 114ff); learning becomes problem-solving.

Gregory (1980) formulates a theory of **perception as unconscious hypotheses construction**, defined as “*selections of signalled and postulated data organized to be effective in typical and some novel situations*” (ibidem, p. 184), “*fiction generators which may hit upon truth by producing symbolic structures matching physical reality*” (ibidem, p. 182). Perceptual hypotheses are coded signals with predictive power, and they can be confirmed and disconfirmed though not with certainty; percepts are tied up with language that codes signals, which depend as much on what is as on what may be the case. Compared to scientific hypotheses, perception is from a vantage point and in real time, of instances not generalizations, about concrete objects, predictive not explanatory, and aware as percept. We are conscious that we see a dog. However, the perceptual

field is full of ambiguities, distortions, and paradox features, and we recognize them as false hypotheses arising from best fit. The perceptual field is not Euclidian, in the sense that parallel lines never meet; this is only the case in the near visual field, wider afar lines converge. According to this account, perception moves from signal and data to hypothesis which periodically misfires when the physical reality diverts from the experienced one. The hypothesis is the **end point of the process of coding signals**; the percept offers the best fit.

For others, the problem becomes, how psychological dispositions (attitudes, cognitions, schema, perceptual or effective hypotheses) change across time and situations. Piaget (1972) explores an **ontogenetic development theory of schemata** which temporarily stabilize by equilibrating between phases of assimilation and accommodation. In the assimilation phase, the child is working from a temporary hypothesis as if “*X[animal] is wowow*,” thus until further notice the current schema X[cat] absorbs various acoustic cues in the expected category [cat]; this works up to a point until accommodation sets in and extends the schema to “*X[animal] is miao*,” introducing a differentiation between [cat]miao and [dog]wowow. The “as if” assimilation can be widely off the mark; it allows for playful engagement with reality when the child rides a *broom* as if it were a horse. A sinister function of assimilation arises in the willful extension of a category to a wider range of things simply because one can. A famous Chinese story tells of court officials calling the present offered to the Emperor “what a marvellous stag!,” while being a horse. Insisting on calling a horse as “horse” then becomes an expression of disloyalty in the face of power that is punishable by death. Insisting on the power of imagination can be a power game.

For Miller, Galanter and Pribram (1960), the hypothesis became the image that guides perception as well as the action. The action scheme offers structure in both directions, thus **framing perception and action**. The image guides the perception of relevant cues; the plan offers behavioral choices towards the goal. In regulating goal-directed behavior, hypothetical results are feeding

forward as goals which are continuously compared to current affairs through feedback, until the gap of “is” and “ought” closes; if it ever closes as the “ought” is part of a self that moves in co-ordination with others (Prinz 2012). Competent social activity involves the flexible matching of percepts with plans of behaviors from a stock of proven “if . . . then” observations. This allows to recognize different ways of why peoples make mistakes: category errors on X, planning errors on Y, and lack of skills, i.e., percept-motor schemata X-Y.

What for science is a tool, became for psychology the theory: **humans are intuitive statisticians**. Minds work by testing hypothesis to make causal attributions, judgments under uncertainty and risky decisions (Geigerenzer 2020). The computer as a calculating machine becomes the core metaphor of this theory. The subjective mind is benchmarked against “formal-objective calculation” and characterized by its various deficits and biases against the norm of reaching conclusions in one best way. For some, this wins a Nobel Prize in Economics (Kahneman 2011); for Geigerenzer et al. (1989), this amounts to unjustified intellectual imperialism.

Groner (1978) had earlier offered a different example of this looping modeling: a hypothetico-deductive theory about ordinary people solving problems by using heuristics (Groner et al. 1983). Cognition is modeled mathematically as **progressive hypotheses reduction** along different paths of problem-solving. This involves strategies for focusing, testing, and discarding rivals within sets of possibilities. It also deals with the storage of falsified or confirmed hypothesis in memory. The theory involves three entities: hypotheses, input information, and an evaluation criterium. For a problem task, the space of all possible hypotheses H is larger than those relevant for a person Hp. Equally, all available information I is larger than the relevant information for person Ip. Thinking is progressing across sets of Hp/Ip and reducing the number of relevant hypotheses. Different paths of problem-solving are mathematically formalized to make predictions about type of solution, response latency, and attention focus. Problem-solving is an embodied but subconscious

process for the study of which specific techniques of eye movement tracking were developed [ibidem, p. 177]. This theory postulates nine ways of hypotheses processing, thus working against the ritual of testing against only one best way (Groner 1978, p. 174).

Possibilities Beyond Hypothesis

This chimes well before its time with recent calls in psychology to limit the vacuous ritual of statistical testing and to spend more time on conceptual developments and measurement (Scheel et al. 2020). Debruwere and Rosseel (2021) go even further and suggest ditching the hypothetico-deductive method altogether, and to reduce the experimental efforts in favor of collecting more data, from more populations and across more situations. The model science is no longer astronomy or subatomic physics but meteorology and biological taxonomies where local observational data precede mathematical modeling (see Fassnacht 2000; Bruner 1974, p. 462).

Another glance beyond hypotheses arises from the experience of hermeneutics, the science of text interpretation, which avoids altogether the monological-operational language of hypothesis testing (Gadamer 1975; 3ff). All text interpretation is guided by **prejudice** and a **cultivated attitude of openness**. This allows expectations to be frustrated and the reading to be inspiring. The need for prejudice arises from the impossibility of a prejudice-free approach; all reading starts from a lived pre-understanding, not something you put there [i.e., hypo-thesis]. The hermeneutic circle moves from a naïve start and what seems very strange reading to a second step, where the unfamiliar is assimilated and rendered familiar; only a third cycle opens to the text on its own terms as if in dialogue with another person. New understanding arises from a **fusion of horizons**, when the reader experiences the text as an enriching encounter with transformative effect. The initial prejudice can be inhibiting and reproductively confirming your prejudices; or reading a good book can inspire and turn you into a different person. The hermeneutic experience rehabilitates

tradition and authority as productive constraints (ibidem, 277ff). The interpretive enthusiasm must chisel away at the canon of tradition and the dogmas of authority in order to avoid the madness that arise when working without constraints and under the guidance of “anything goes.”

While hypothesis testing is a monological strategy seeking ego-centrally effective interventions in the world through control and predictions, hermeneutic efforts are oriented dialogically towards reaching a common understanding among people who engage the world as if it were a text that speaks (Habermas 1989; Blumenberg 1986).

Summary

In summary, we can say that the term “hypothesis” marks a space of possibilities in several ways. Firstly, it is the uncertain starting point from which firmer conclusions might be drawn as in public reasoning. Secondly, the hypothesis is the logical end point of a process of firming up on reality through scientific enquiry. Thirdly, hypothesis is a point of transition that calibrates perception and social interaction. And finally, hypotheses might be part of a monological ritual of reasoning that distracts from reaching a common understanding about the world and its utopian possibilities.

Ideology

Kevin R. Carriere
Washington & Jefferson College, Washington,

Abstract

Ideology is a term frequently used though rarely defined, having its historical use traced to the late eighteenth century. While used as a synonym for political beliefs, ideology exemplifies deeply engrained scripts for how one chooses to interpret the world. While most research has focused primarily on the content of ideology (what value a conservative might hold, what traits define a liberal), there has been a recent call to explore the doctrinal and relational components of ideology instead. In this way, research can better understand not just what ideology is, but how ideology maintains and permeates itself across individuals and groups. The existence of ideologies requires the consideration of utopias yet to come. Future research gives us the opportunity to study ideologies and utopias by examining revolutions in the toppling of governments, in the changing of workplace norms, and in the individual who resists conforming to existing ideological beliefs. Reflections on the possibilities of how future research in this field can be developed are suggested.

Keywords

Ideology · Utopia · Possible ideologies ·
Revolutions · Doctrinal · Relational

Introduction

The possible interpretations of what ideology “is” are vast and nebulous. It has been called “one of the most ubiquitous concepts in modern political thought” (Mullins 1972, p. 498). The concept has found a similar fate in psychological research, rarely being defined yet functioning as a critical concept in political psychology, which frequently interprets it as synonymous with political beliefs. Yet, ideology is much more than being liberal or conservative. Its expansive possible definitions permit a more nuanced understanding of not just the content of the belief systems, but also the structural, historical, and meaning-laden construction of such belief systems. This entry will start by defining ideology and examining how it has developed over time.

History of Ideology

The history of ideology traces itself back to 1796, when Destutt de Tracy used the term as meaning a “science of ideas” (Kennedy 1979; Lichtheim 1965). Napoleon, and later Marx, took the term as a pejorative descriptor against his opponents as

ideologues (Drucker 1972). In sociology, Karl Mannheim built his understanding of ideology into two categories – of the partial, and of the total (1938)¹. In partial ideologies, disagreements can exist, but there still exists a shared intersubjective worldview between speaker and listener, such that both parties can agree on what is a lie, and what is the understanding of truth. If false beliefs or statements occur within a partial ideology, this is attributable to the human nature of individuals, not any maleficence by the individual. We live our lives in partial ideologies – it is our way of understanding the world.

On the other hand, total ideologies describe situations when thought systems are so divergent that the fundamental ways whereby two individuals experience and understand a particular event can be totally incompatible with each other (Mannheim 1938). In this way, a “total ideology” would not include models of thinking such as scientific thought, which require the shared goal of seeking truth and having a common language under which to communicate. Instead, total ideology includes both the formal and informal systems that maintain the status quo and direct our understanding of the world toward certain trajectories and away from others. Western interpretations of the world are influenced in large part by a capitalistic, patriarchal, and white supremacist mindset. Any challenges to such a system are fundamentally rejected and considered incompatible, improper, and potentially even misleading. The fury currently erupting in the United States over “critical race theory” and its attempted bans within public school systems is one example of how total ideologies continue to stake their power in the individual’s everyday experiences. Other researchers have expanded this view of total ideology as a false consciousness – the willingness to support a worldview that one incorrectly believes benefits themselves (Eyerman 1981; Jost et al. 2014). Marx’s belief in the downfall of capitalism was not realized because, according to Eyerman (1981), the people had bought into the false

consciousness of capitalism, believing they (and their children) would someday reap the rewards of the system.

Mannheim placed ideology in contrast with utopias (Mannheim, 1938). Ideologies are worldviews that maintain the status quo, while utopias are possible futures that work to overthrow the current system (Kashima and Fernando 2020). If such a utopian revolution were to succeed in overthrowing the current ideological creation, it would result in such utopias becoming the next ideology, waiting for their turn to be overthrown. Utopias are not-yet-realized ideologies, where the determining factor of what becomes an ideology and what remains a utopia is strictly determined by the society on which is currently being used by the majority in-the-moment. While ideologies are oriented to the past and as society *is*, utopias are oriented toward the future of as society *could be*. This cycle of constant ideological revolution has been discussed in terms of rights and duties (Moghaddam 2004) and forces us to consider the historical context of ideologies, which at one point were more than likely a utopian idea at one point in time, awaiting their moment to emerge as an ideological foundation.

Mannheim’s view of total ideology as a form of maintaining the status-quo fits into the mainstream psychological perspective of ideologies as a method of system justification (Jost 2006; Jost et al. 2014). Ideology is not simply the dominant mode of thought (“capitalism”) but its active participation in ensuring that the (“capitalistic”) mindset survives and thrives in each future moment (Augoustinos 1999). For example, in a series of studies, Jost et al. (2014) show how part of the function of religion is to provide justification for the existing social order to establish not only legitimacy, but also to establish that religion is worth preserving for future generations.

Sampson (1981) noted that within psychology, ideology had been developing in two different ways. First, it is used as a term of false consciousness, where the ruling class’s material interests are hidden through ideology to keep the status quo intact. And at the same time, it also was being used to “accurately represents the consciousness of a group or an epoch” (p. 731). In considering

¹For a review of Mannheim’s work on ideology, see Hammersley 2021.

how ideology could both represent falseness and truth, Sampson argued it is true in how the subject experiences it, yet what the subject is experiencing, i.e., the object of experience, can be false in so far as it maintains a systemic inequality between two groups of individuals. To study just the individual leaves one blind to the systemic barriers and limitations maintained by the status quo, yet to study solely the status quo ignores the individual who engages, participates, and contributes to the maintenance and upheaval of a given ideology. Researchers need to consider how the individual contributes and engages with the various meaning systems around them, providing the opportunity to consider an individual who both accepts and rejects the current ideology at any given moment. In a study examining how young children negotiate gender relations, equality, and feminism, Rogers (2020) provides an example of the equivocation of ideology in a second grade girl discussing the importance of being a girl while recognizing the burdens of the current ideology to keep her behavior in line with the status quo:

She explained that being a girl is important to her because ‘we get to pick girl stuff. . . That we could take what we want. But, not the stuff for boys.’ When asked what she does not like about being a girl, this second-grader said: ‘That we don’t get to pick the stuff that we really want. You’ve got to pick girl stuff instead of what you want’. (p. 187)

Yet, this engagement with the meaning-systems surrounding ideology has frequently led to latching onto specific political meaning systems. As time passed, the definitions of ideology and “ideological beliefs” became intertwined, as “being ideological” was tied with being politically sophisticated or knowledgeable in politics. Political scientists have consistently drawn from the definition of ideology as a stable and coherent belief system (Converse 1964), while others used this definition to argue that the average person cannot be “ideological,” since their positions on a range of topics are so ill-informed, shallow, and random (McGuire 1986). Psychology has done little better, defining it as a collective belief system that gives meaning to *political* behavior by organizing one’s values (Jost 2006). The

interchangeability of “ideological beliefs” and “political beliefs/behavior/thought” has led research to fail to consider the everyday life of (in)formal belief systems outside of the political realm (Augoustinos 1999).

The large majority of the research into ideologies has frequently been in conjunction with political belief systems. However, nonpolitical research does exist, and has expanded ideology to frame issues of neoliberalism (Bettache and Chiu 2019), feminism (Rogers 2020), white supremacy (Nogueira 2013), religion (Jost et al. 2014), color-evasive racism (Annamma et al. 2017), and ethicality (Galvin and Herzog Jr. 1992). This is not to dismiss any of the above as nonpolitical. Many of these issues may have their own political angles in discussions around freedom of religion, of group dominance, and of the rights of minorities, to name a few. Yet, these ideologies remain qualitatively distinct from pure behavioral and attitudinal differences of individuals on different portions of the political spectrum.

Ideology As Master Narratives

The term “political” often refers to the negotiation of self with others and otherness (c.f. such use in political imagination, Glăveanu and de Saint Laurent 2015). Yet, ideology does not need to operate in negotiation of others and otherness. Some ideologies – such as *The American Dream* – operate based on the individual and their interaction with their own future possible selves, external to the interactions of others. Instead of positioning toward others, ideologies can very easily position individuals in terms of how they make sense of the world around them. Ideological thinking may be considered as a type of master narrative (McLean and Syed 2015), deeply engrained scripts for how one chooses to interpret the world, with what positions, and what histories are brought forward and what futures are held back.

Master narratives are created by groups, for groups, and molded and used by individuals within these groups. Ideologies as master

narratives shape who we are and how we interact with those outside of our own ideologically defined spheres. And yet they have implications for how we teach historical truths (Carretero 2018), how we remember past events, and how we imagine the future (Obradović 2018). In an analysis of high school textbooks, Alridge (2006) examined how the master narrative of Martin Luther King Jr. sought to promote only certain portions of his life, choosing to ignore the more complex and complicated sides of his history. Other researchers have continued to explore ideology as a master narrative, examining how master and alternative narratives of gender can influence how children either disrupt or support gender inequality (Rogers 2020).

Master narratives also provide the opportunity to consider not simply the formal belief system of *capitalism*, *conservativism*, or *the patriarchy*, but also the informal systems that help maintain such formal systems. Menstrual products are taxed in the United States, as if they were an optional, nonnecessity, in comparison to the non-tax status of most food. But informal systems are not always so explicit – the “old boys club” of various industries; the disparities in pay based on race, class, or gender; the existence of unpaid internships and the affordability of being able to live without an income. All are informal systems that seek to maintain the status quo and support the formal system that exists in society. They echo parts of the master narrative that remain unquestioned, assumed, and non-challenged as “the way things are.” The informal systems within an ideology can be better understood within the larger socio-ideological context.

In her study of children’s beliefs about gender equity, Rogers (2020) noted four approaches to engaging with the ideology of gender roles. Two, “genderblind” and “differences,” existed to promote the master narrative of inequality, and the other two, “incongruent” and “counternarrative,” functioned to promote the utopia of equity between genders. Children who spoke through a differences-based narrative, where they talked about the differences between girls and boys, and felt that their friendships and interests would change if they were a different gender. They were

more dogmatic in their understanding of gender differences, and any claims to challenge the system (a girl saying, “Pink is better than blue!”) does nothing to dismantle the system of inequality and access to a wider range of colors. Compare this master narrative with those who engaged in a *counternarrative* discussion. These children actively noted the relational issues around gender inequality and stated that their goal was to prove it wrong. If they were to discuss the system of colors, individuals who used a counternarrative framework may say things like “I will wear whatever colors I like, and you should too.”

The Master Narrative of the American Dream

The narrative of the American Dream is a key component of a North American identity holding a large amount of power over how one considers future job opportunities, illusory hopes for unobtainable futures, and even how we take care of our elderly population. This belief that anyone can be successful and move up in economic class rankings through hard work and determination, and that future generations will be better off than your own can lead to critical meaning-making outcomes. Those who were led to believe it was easy to move upward in socioeconomic status were more willing to endorse income inequality than those who were lead to believe it was very unlikely to move up in socioeconomic status (Shariff et al. 2016). This effect was also shown at the macro-level, where countries that had higher socioeconomic mobility were more likely to also support income inequality.

Ideologies such as “the American Dream” can lead to political considerations such as believing one will eventually “make it rich” and therefore, reduce one’s incentive to want to tax the rich. The marketing and propaganda generated around “The Death Tax,” (the repeal of the estate tax in the United States that effected just a tiny minority of individuals) led to wide support from a range of individuals, many who would never benefit from its repeal. These ideologies can also direct the individual to consider their futures in overly

optimistic ways, where both noncitizens and naturalized citizens are more likely to believe they will achieve the “American Dream” than citizens (Cohen-Marks and Stout 2011).

The functioning of the ideological content of *The American Dream* is one that on its formal level promotes hard work, independence, and self-reliance. Yet, informally, within such an ideological narrative is one of community exclusion, of low worker support, and of minimal acknowledgment to the differential positions of power of each individual person within the society. Yet, even though such a dream is difficult, and even impossible for some individuals within certain neighborhoods and socioeconomic statuses (Chetty et al. 2018), the American Dream remains a stable master narrative in the American mind across generations (*Opening Doors to Opportunity: Generation Z and Millennials Speak*, 2020). The process of survival and maintenance of the master narrative of an ideology is just as important to understand.

Beyond Ideological Content to Ideological Structures

A large portion of psychological research focuses on ideology as political identification and beliefs. In an effort to sidestep this problematic approach to ideology, this entry proposed a definition that goes beyond any specific content of a belief and focuses on the overarching structure of what makes up an ideology— that of collective stories. Yet, regardless of either approaching ideology as a political system of thinking or a master narrative of storytelling, both of these definitions may lead researchers to consider “what” the story is, or “what” the ideological differences are, and not necessarily any large exploration and understanding of how the individual *engages* with such stories. In the next section, this entry outlines work that seeks to expand the study of ideology from a content entity to one of structure.

In reviewing the state of ideological research, Zmigrod (2020) suggests that psychology has long examined the content of ideological beliefs (do you hold democratic or conservative values)

and should instead examine the process of how ideological thinking comes to be. Zmigrod (2020) identifies two main characteristics of ideology: doctrinal and relational. Ideology is rigid to its doctrine and averse to new evidence. Second, Ideology is also relational – it is oriented toward providing preferential treatment based on group membership. This *doctrinal* and *relational* approach to examining ideologies provides researchers with the ability to move beyond the content of the ideology (i.e., is it a system of thinking based on political power) toward new possibilities. In doing so, one can examine the range of ideological thinking by exploring the rigidity and identity salience of the individual as they interact with an investigated ideology. Instead of considering how one’s political beliefs predict support for a given issue, more attention can then be given to how strongly they identify with their political beliefs (Espinosa et al. 2018) and how deviants might be treated who may not hold such strong beliefs (Allamong and Peterson 2020).

Ideology As Doctrinal

The doctrinal aspect of ideology has also been examined under the term *ideological strength* (van Prooijen and Krouwel 2017). The benefit of using such a concept of ideological strength is that it allows ideology to vary on its salience. For example, while a content-focused ideological view would consider conservative ideology as a cognitive driver on an individual’s decision making at each moment (Jost et al. 2003), the doctrinal-focused ideology provides an understanding of how such ideological thinking can change, based on an identity that is currently prevalent within the individual’s mind (Fischer et al. 2010). It also provides a more holistic understanding of the range of ideological thinking by considering not just ideological member affiliation, but how strongly one identifies with ideology X as it relates to their momentary decision making.

By examining ideology’s rigidity, we can examine the evolution of ideologies over time. If an ideology is more rigid in accepting new ideas and change, it may further double-down in their

beliefs when challenged, leading to more extremist tendencies. The transformation of the Republican ideology in the United States is a prime example, where the requirement to support the “Big Lie” in the outcome of the 2020 election has led to the ousting of its own leaders. On the other hand, ideological rigidity necessitates the examination of the ductility of an ideology by examining the contexts and criteria necessary for the breaking point of one ideology into many. The ideological goals of revolutions frequently lead to group fractures – the Mensheviks and Bolsheviks of the Russian Revolution, the Jacobins and Girondins of the French Revolution. In both, the rigidity of a new ideology breaks, spawning new ideological goals and imagined futures. Under what conditions the rigidity of ideology fails to unite its members needs further psychological explanations.

Psychology can assist in this endeavor by examining the micro, individual-level experience of ideology. The existence of places such as Christiania in Copenhagen as an anarchistic commune shows that in small pockets of the world, the ideological presence of capitalism has been overturned. The negotiations with its members, its community, local police, and local laws that ensure the future existence of Christiania and similar communes are rich psychological arenas. The Danish government required the residents of Christiania purchase its own land; an action which itself stands in stark contrast to the ideal of non-ownership, yet is required for their ideology to continue its existence.

Ideology As Relational

The benefit of the relational component is in the directionality of ideology. Ideological thinking is not a stagnant function. It engages with someone or something for some purpose, be it system justification, power manipulation, or self-preservation. This relational component of psychological processes has been explored in a variety of other areas, including collective action, legitimacy, and general issues of discrimination and prejudice. For example, van Zomeren (2015) considered how collective action is a way to regulate social relationships with others. In

considering the relational component of ideology, research considers not simply how the individual negotiates with the macro-level (in making one’s utopia their ideology), but also how they might engage with others within the system. The relational component of ideology allows for an understanding of how various symbols and signs, such as a Make America Great Again hat or a bumper sticker on a car, can identify people with the stories they both carry, and, perhaps more importantly those they do not.

Research into a more content-driven understanding of ideology still can be done, but requires a consideration to how the individual weaves their own personal story onto how they interpret and understand the ideology in that given moment. Instead of asking, “On a scale of extremely liberal to extremely conservative, where do you fall?”, one can ask “What does being extremely (liberal/conservative) mean to you?”. This allows a larger perspective on understanding the individual differences within an ideological framework. Since research itself cannot center on a single definition of ideology, it is hypocritical to expect individuals to be able to accurately place themselves on an ideological spectrum. This allows for a deeper understanding of the various shades of a given ideology, if only research were to explore the possibilities within ideological diverse groups.

Possible Ideologies

The intersection of ideology and possibility is rooted in a contrast between ideology and utopias, and their cyclical nature leaves the existence of possible ideologies as utopian. For a greater psychological understanding of what ideologies are, this entry considered going beyond political modes of thought toward master narratives that guide both how we recall the past and how we imagine the future. In doing so, it noted the importance of considering both the doctrinal (how rigid is this narrative) and relational (how does this narrative create differences between groups) components of ideology. In this section, we return to consider utopias – possible ideologies that are not

fully realized by the majority – as a way to further research the psychology of ideologies.

Utopias are pushing to make change to the current master narrative, trying to write the next page of history in their own way. They are future-facing revolutions of the status quo, striving to overturn the current ideological system. A fully realized utopian revolution would result in what Moghaddam calls a fourth-order revolution (Moghaddam et al. 2020). This type of revolution includes a change in leadership, mass-mobilization, and changes in both the formal and informal systems to properly achieve the goals of the revolution. While examples are difficult to find at the macro-level, such utopian victories can be examined through exploration of unionization campaigns in a workplace. Such campaigns involve a change in leadership (the workers get control of their terms of employment), mass mobilization (for voting, striking, and collective action), the formal system (creating and changing the terms of employment), and the informal system (clarity of workplace expectations).

This could be why utopian ways of thinking are negatively correlated with system justification motivation and more supportive of changes to the current society (Kashima and Fernando 2020). Utopias are the lived experience of the individual, regulating the hegemonic systems that pervade and guide our thoughts and behaviors. New ideologies where utopias emerge in response to a collective discontent within a given political order center on issues around power dynamics, of rights and duties, or of distrust in the current state of affairs (Moghaddam 2004; Moghaddam et al. 2020). Revolutions in one's way of life, in one's workplace, in one's country, all present ways under which we can explore the shifting of ideology to a new utopia and subsequently new ideologies.

Conclusion

Ideology is a term frequently used but rarely defined. Its historical use as substitute for political positioning and knowledge has distracted research from a larger conversation around its

presence as a master-narrative. Ideologies, considered in the framework of master narratives, are deeply engrained scripts that act as ways for how one chooses to interpret their world through their positions and what histories are brought forward and what futures are held back. While most research has focused primarily on the content of ideology, there has been a recent call to explore its doctrinal and relational components instead. The existence of ideology requires the consideration of utopias, of ideologies yet to come. Future research has the opportunity to study ideologies and utopias by examining revolutions – not just at the macro-level in the toppling of governments, but at the individual level resisting gender norms, or at the meso-level of a revolution at work.

Faust, Dover Thrift Editions (2018), Trad. by B. Taylor; p. 32*

*At the simplest level, only people
who know they do not know everything
will be curious enough to find things out.
Virginia Postrel,
The Future and Its Enemies, Touchstone Edition (1999), p. 88.*

Abstract

Ignorance is an inherently broad and comprehensive notion, which, ironically, can refer to both the worst enemy of science and knowledge-related efforts and, in its Socratic form, their best ally. Indeed, by understanding the concept of ignorance, one can discuss a variety of topics, such as error, falsity, and prejudice but also surprise, wonder, and creativity. Unsurprisingly, so, the current research about ignorance is varied and interconnected. Thus, this chapter will be divided into two main sections: the first will be dedicated to a brief presentation of the different research areas that shape current ignorance studies; in the second section, a few questions will be asked: What can we do about our ignorance? How can ignorance be exploited and become useful? How can ignorance define the limits of our possibilities? Even if the answers presented in this chapter will not provide an exhaustive picture

of how ignorance interacts with human chances, they will hopefully offer suggestions for further steps in its analysis and investigation.

Keywords

Ignorance · Epistemology · Philosophy · Cognition · Knowledge · Reasoning · Psychology · Limits · Limitation

Introduction

At first glance, ignorance is an everyday topic that needs no further introduction. Notwithstanding its intuitive meaning, from a layman's view, at least two very different approaches can be used to approach it. Like the long-known villain in a fairy tale, ignorance, if willingly cultivated and exploited, can represent an easy target of contempt and therefore be condemned without question. Conversely, ignorance can also be associated with a positive human character: humility or the Socratic virtue of knowing our limits. In this case, ignorance is something everybody should acknowledge about oneself: to know oneself to be ignorant is the first step to bettering oneself, to learning, and to overcoming partial perspectives.

Both these versions reflect certain aspects of the notion of ignorance. Indeed, in most cases, if people are willingly ignorant, they deserve blame for it. On the contrary, if people are unwillingly or unconsciously ignorant of something and they aim at improving their knowledge, their efforts should be appreciated. Of course, the world is not as black and white as this brief introduction to the topic would suggest, and intuitively we can appreciate that not all willing ignorance brings blame (the double-blind review policy is an easy example of not blameworthy willing ignorance), and not all attempts to fill the gaps of one's ignorance should be praised (the act of cheating in a game usually involves getting to know something that one should not know yet). In any case, the distinctive moral inclinations toward two different accounts of the everyday use of ignorance should prove how inherently broad and comprehensive this notion is. Indeed, this assumption is evident even without considering more morally tricky

cases in which the role of ignorance is highly relevant, as the topics of error, falsity, and prejudice but also surprise, wonder, and creativity.

Thus, even if ignorance can at first appear like a straightforward and atomic notion, it incorporates a variety of nuances, degrees, and shades that make it a convoluted idea, which, like knowledge (and knowing), can hardly fit in a one-line definition. Indeed, the current research about ignorance is intricate, varied, and interconnected (as proven by those special issues and handbooks dedicated to the topic, Arfini and Magnani 2020; Gross and McGoey 2018): for this reason, this entry will be divided into two main sections to acknowledge the variety and complexity of the literature on ignorance.

The first will be dedicated to a brief presentation of the different research areas that shape current ignorance studies (which pertain to the studies of ignorance as an abstract concept, the action of ignoring, and the categories of ignorants); the second section will be devoted to the interaction of ignorance to the idea of the possible. A few questions will be asked: What can we do about our ignorance? How can ignorance be exploited and become useful? How can ignorance define the limits of our possibilities? Since what is and what *is perceived* as possible change as much as our ability to obtain new knowledge, expertise, or competence, ignorance represents both a limit (a boundary that we cannot pass) and a limitation (a boundary that we can overcome) to our possibilities. Far from restricting the entry to a negative approach to ignorance (i.e., viewing it as something that merely restrains cognition), this last section will also present ignorance as the ground from which creativity in reason and action emerges: how to come up with new ideas and hypotheses depends on how we approach our ignorance and what we do not know yet. Moreover, ignorance can also be connected to the concept of unexpectedness and our reaction to it: something that we did not expect can trigger different epistemic and emotional responses, such as wonder and surprise but also fear and negation. Understanding the processes by which we ignore or we are ignorant of something can shed some lights also on how we approach unforeseen

possibilities. Thus, even if the answers presented in this chapter will not provide an exhaustive picture of how ignorance interacts with human chances, they will hopefully offer suggestions for further steps in its analysis and investigation.

Ignorance Studies: One Concept and Three Distinct Perspectives

Thus, ignorance is a broad term that describes a plurality of circumstances and conditions. Evidence for the broad significance of the term rests on the definitions provided in the dictionary for its related terms: to be *ignorant* and to *ignore*. Notwithstanding the common etymology (from the Latin *ignōrāre*, not to know), the two words express different perspectives from which it is possible to analyze at least two distinct conditions and typologies of ignorance (while the noun “ignorance” encompasses both meanings).

From the Oxford English Dictionary (Stevenson 2015), to be *ignorant* is defined as to be “destitute of knowledge, either in general or with respect to a particular fact or subject; *unknowing, uninformed, unlearned*” (added emphasis). Instead, to *ignore*, in the most common use, is defined as the action of “refusing to take notice of; not to recognize; to disregard intentionally, leave out of account or consideration, shut ‘one’s eyes to.’” These definitions are interestingly different because they can describe not only two different points of view on ignorance but they can also describe different types of ignorance altogether. If “to ignore” is taken as “disregarding intentionally” something, then people who ignore are bearer of different ignorance in comparison with people who are ignorant because they are unconsciously and unintentionally poorly informed. To be precise, this second category of people do not ignore something, but they are ignorant of it. Using ignorance to cover both these situations drives then to merge conflicting and different cases. For this reason, the nuances in the terminology of ignorance have also determined different approaches to the theme. Briefly put, indeed, ignorance studies revolve around three main areas of interest: the logical, cognitive,

and epistemological description of ignorance; the investigation about how others' ignorance is exploited; and blurred instances of ignorance as a mix of being ignorant and ignoring.

Logical, Cognitive, and Epistemological Descriptions of Ignorance

What does it mean to be ignorant? Are there gray areas between ignorance and knowledge? The first research area encompasses the attempts at enucleating logical, cognitive, and epistemological descriptions of ignorance. These attempts reflect on the broad and encompassing concept of ignorance while focusing on particular viewpoints. Usually, for example, logical formalizations of the concept of ignorance tend to concentrate on specific instances of the term. Some logical reflections focus on ignorance as an action that the agent performs (S ignores P) or an epistemic state (S is ignorant of P) that defines the agent in comparison with others (Carrara et al. 2019; Van Der Hoek and Lomuscio 2004; Gargov 1999). Also second-degree ignorance (S is ignorant that S is ignorant of P) is encompassed in this typology of studies.

Epistemological examinations of the term in this field brought on a now well-known divide in the literature: the separation between the standard view – which sees ignorance as the absence or lack of knowledge – and the new view, which describes ignorance as the absence or lack of true beliefs. The difference between knowledge and true belief is a matter of philosophical nuances. Knowledge is commonly associated with *true and justified belief*. A true and justified belief is, for example, my belief that I have a computer: I do in fact have a computer, and I have good justification for believing so because I am using it to type. If one refers only to true belief, one refers both to *true and justified beliefs* and *not justified* ones: if a tarot reader tells me that I'm infected by measles because her tarots tell her so, her belief can be true without being scientifically justified. So, the standard view assumes that ignorance is the opposite of knowledge and that ignorance and knowledge exclude each other (Haack 2001; Le Morvan 2011; Zimmerman 2008). Instead, the new view on ignorance sees

ignorance as contrary to true belief: you are ignorant only if you do not have a true belief about something (e.g., in the case above, if I was infected by measles, my tarot reader would not be ignorant of that). Authors who argue for this thesis deem that none of the cases of true beliefs that fall short of knowledge are cases of ignorance (Guerrero 2007; Peels 2011). From this perspective, the label of ignorance is attributed to fewer situations and merges cases of factive, procedural, and objectual knowledge in propositional knowledge. Although these definitions bring understanding about the nature of ignorance, they remain within the boundaries of an internalistic view of both ignorance and knowledge, and they disregard cases in which ignorance and knowledge merge (as in misunderstandings, misconceptions, and disinformation).

In response to these problematic limits, some authors attempted to find descriptions of ignorance that encompass an externalist perspective and merging conditions of ignorance and knowledge (in particular, Arfini 2019a, b; Werner 2019 see also ► [“Extended Mind”](#)). In brief, these studies analyzed “ignorance” as a cognitive condition that variously affects the metacognitive, inferential, and social abilities of the agent. While this view has the merit of encompassing a broader range of instantiations of ignorance, it brings out also a weaker definition of it, since it does not depend on a strong concept of knowledge, belief, or even truth.

While these last perspectives provide food for thoughts regarding ignorance as “being ignorant of,” they do not explicitly regard cases in which ignorance as “ignoring” or “favoring others to ignore something” is considered (excluding the logical reflection). Another type of analysis arose in the last decades to consider these cases.

The Exploitation of Ignorance

Do prejudice and privilege bring forth forms of ignorance? Are not racism, sexism, ageism, and other forms of bias and discrimination entangled with ignorance? Is not a socially partial perspective an inherently ignorant one? These questions have been analyzed and posed by a second broad area of ignorance studies, which incorporates the

sociological, anthropological, moral, and cultural analysis of instances of ignorance as a result of contextual settings and manipulations.

Indeed, ignorance, seen as a pair of conceptual and multipurpose blinkers, brings out four main keywords, which designated the research in these areas: “situated knowledge” (Haraway 1988; Stoetzler and Yuval-Davis 2002), “epistemologies of ignorance” (Sullivan and Tuana 2007; Tuana 2004), “agnotology” (Pinto 2015; Proctor and Schiebinger 2008), and “strategic ignorance” (Gross and McGoey 2018; McGoey 2019). The first one emerged in feminist literature when Donna Haraway (1988) denounced the partiality of academic and scientific community’s view by approaching the flaws of the concept of “objectivity.” Haraway concentrated her attention on that term because while in theory it referred to an absolute, impersonal, and disembodied scientific perspective, it was actually incorporating and justifying a partial point of view, which embedded the viewpoint of the rich white men whose vision of science was embed in a colonialist, capitalist, militaristic, and supremacist mindset. Unveiling the partiality and hypocrisy of this point of view, Haraway began to approach a topic that now permeates some currents of the studies of ignorance, the “epistemologies of ignorance,” that now aim at finding out partiality and biased construct in scientific research and in the aims of scientific progress.

The authors that follow the research program of agnotology, instead, concentrate on broader settings: they define ignorance as the outcome of social and cultural environments, in which some strategic behaviors limit the knowledge, understanding, and epistemic grasp of parts of populations (Proctor and Schiebinger (2008); Gross and McGoey (2018); McGoey (2019)). A way to explain the reach and range of agnotology investigations is to appeal to the words of one of the authors who coined this word (Proctor and Schiebinger 2008, p. 15): “Why don’t we know what we don’t know?” to which in many cases the answer is ‘because steps have been taken to keep us in the dark!’”

As this area of research grows, it has advanced the understanding of how ignorance *circulates*, or

it is *produced* in order to be *distributed*, in populations that share the same culture, same values, and same epistemic or normative principles. In this circulation, obviously, ignorance cannot be easily represented just as the opposite of knowledge or as lack or absence of true beliefs: it also incorporates parts of understanding, knowledge, and information, as well as the active act of ignoring. To comprehend how ignorance can assume these hybrid forms, another miscellaneous area of inquiry has beginning to appear in the current philosophical and psychological literature.

Misconceptions, Misunderstanding, and Other Blurred Instances of Ignorance

Besides the first two areas of research, another type of investigation has been flourishing in the last decade: the philosophical and psychological study of particular occurrences of ignorance. The point of interest in this multifaceted research field is “how” and “with which consequences” one can be in part ignorant of something and in part actively ignoring it.

For example, a line of study investigate how we can distinguish rational and irrational willing ignorance, and, in turn, the latter can be described as motivated or unmotivated (Caplan 2001; Somin 2015; Williams 2019). We can be rationally and willingly ignorant, for example, when the costs of acquiring knowledge outweigh the benefits of possessing it. In other cases, being willingly ignorant can derive from typically considered irrational conditions, such as self-deception, akrasia, and wishful thinking (Bortolotti and Cox 2005; Chang and Bridewell 1998). Philosophical as well as psychological studies about these conditions aims at establishing how much the agent could and should change her epistemic status.

On the same line of investigation, we have studies regarding errors of reasoning, fallacies, biases, and heuristics (cf. Gigerenzer and Goldstein (1996); Tindale (2005); Woods (2013); see also ► “Abduction,” ► “Heuristics”). All these phenomena share the common feature of being both ignorance-based – we err, or trust a fallacious reasoning because we lack some cognitive resources, such as pieces of information,

computational power or time to get more data, and ignorance preserving – once we perform the reasoning, we cannot be sure of our errors or if our hypotheses were correct unless we analyze and perform them again. These studies brought about some interesting questions regarding superstition (Bertolotti 2015), misconceptions (Dellantonio and Pastore 2020), misinformation (Bessi et al. 2014), and fake news (Spohr 2017), which are important topics also in sociology and epistemology.

Moreover, some studies look closely at the relation between the agent system of beliefs and metacognitive capacities and her ability to assess her own competence. The experimental investigation conducted by Kruger and Dunning (1999) led to one of the most known effects or biases that affects our self-assessment capacity: the Dunning-Kruger effect, which links the lack of skills that subjects have in particular areas of expertise with their high level of confidence in the same areas. On a similar note, in philosophy a collection of recent studies discuss the cognitive bubbles that affect our capacity of self-assessment or the problematic relationship between the agent's belief system and her capacity to assess its coherence and credibility. Below is a brief list of few bubbles currently considered and analyzed:

- The “epistemic bubble,” which describes the situation in which we believe we know something even if we do not know it (Woods 2013)
- The “ignorance bubble,” which describes our tendency to underestimate our ignorance and to overestimate our knowledge-gathering efforts (Arfini and Bertolotti 2019)
- The “moral bubble,” which investigates our inability to justify others' violent moral actions while we do justify our own (Magnani 2011)
- The “religious bubble,” which describes how the typical cognitive praxis of religious beliefs involves their enactment in certain social situations, for instance, moral, spiritual, and rhetorical, but they are deactivated when other kinds of decision or expectations are at stake (e.g., practical expectations, administering one's resources, and so on) (Bertolotti 2015).

All these effects and phenomena deal with the tension between the parts of our ignorance that we can understand and the part that lies beyond our comprehension.

Given the variety of ignorance studies, many are also the ways to discuss what possibilities our ignorance grants us. In the next section, some of those possibilities will be presented, referring to the distinction between ignorance as a limit and ignorance as a limitation of human cognition.

How to Avoid Ignoring Ignorance

To get a useful perspective on the possibilities that ignorance studies bring out, ignorance can be approached as two closely related but distinct categories: the limits and the limitations of human cognition. By focusing on how instances of ignorance belong to either one of the two categories, a few questions will be asked: What can we do about our ignorance? How can ignorance be exploited and become useful? How can ignorance define the limits of our possibilities?

Ignorance as a Human Limit and Chance

A limit is generally described as a point or level beyond which something does not or may not extend or pass: a physical or mental restriction which cannot be overcome (Stevenson 2015). Considering this definition, ignorance can be a limit in more than one sense of the word: in a way, there are things that we cannot know and understand for our physical and mental abilities. We cannot know what it feels like to have a functioning tail nor how it is to have a hive mind: we can describe these situations by referring to our comprehension of the physical structure and behavior of other species, but we know that our hypotheses and theories are limited by our fixed embodied perception. So, ignorance with respect to certain experiences can be understood as an insuperable limit, which cannot be overcome no matter the will and efforts to pass it. Ignorance as a limit of this kind can affect both us as a species and us as individuals: some of the reflections on “situated knowledge” derived from the fact that, within our species, there are points of

view that we as a whole can understand, but not as individuals (Haraway 1988; Stoetzler and Yuval-Davis 2002). Sexism, racism, ageism, and so on are mindsets that represent limits in a sense, since they are impediments that affect the agent's perspective, epistemic resources, and means of understanding. How can we overcome these prejudiced points of view? What are the possibilities that the understanding of ignorance offers to partial perspectives?

These types of ignorance can, of course, be partially overcome by acknowledging, reflecting over, and being aware of these limits. Acknowledging that, physiologically and culturally, some people belong to some sociocultural categories that cannot experience life, in the broader sense of the word, in a similar way to other categories, could at least grant them the possibility of knowing more about their ignorant point of view and others' experience. Moreover, since we all have different cultural histories and different physical limitations and possibilities (which become clear if we consider the difference between the sexes), if we realize that our perspective is limited, we would need to make efforts to understand others and to acknowledge the fact that our perception cannot be a default view (Haraway 1988). To cite a concrete and classical example, the well-known case about the symptomatology of coronary diseases in men and women needs to be considered. Since testing on heart disease was for a long time conducted on male patients alone, specific women's symptoms (which are usually very different from the ones that arise in male patients) were commonly underestimated, leading to serious consequences derived from not having a way to recognizing female symptoms of heart failure (Fehr 2007; Tuana 2006). After recognizing this gap in the medical understanding of coronary diseases, heart failures in women were more easily and promptly found (Emslie 2005).

In the same category of ignorance as a limit, we can also count the problematic epistemology that regards the link between low competence and high confidence, as well as the cognitive bubbles discussed before. They represent a limit that is never actually overcome, but switch from place to place, as much as we collect new experience

and competence: the limit of our competence and self-assessment, in a way, is our epistemic horizon, which we cannot reach, but just know it is there to challenge us.

Usually, a limit defines what someone cannot do: acknowledging one's limits opens the new possibilities of doing something with this knowledge. For this reason, the studies around an externalist perspective on ignorance, the analysis on cognitive and metacognitive limitations, and the investigations conducted in the field of epistemology of ignorance can be illuminating: discussing the effects of unavoidable ignorance can grant us information about how to diffuse and delegate our expertise and knowledge in an open society. The topics in these fields refer to different disciplines, such as epistemology, philosophy of science, psychology, sociology, and political science. All things considered, the open questions are still many: How embodied cognition affects our different gender perspectives? Which default model is used and should be abandoned in scientific research? Should some processes of decision-making be delegated to particular categories of people for the insights that have in comparison with others?

In any case, if our ignorance is in a way the bare epistemic limit that, in turn, defines our possibilities to get new knowledge, in some cases, the same term can describe *limitations* of the human agents, which can be overcome, with, sometime, unexpected effects. The next subsection will discuss the possibilities that agents can obtain when they recognize and overcome ignorance as a limitation.

Ignorance-Based Limitations (and Opportunities)

A limitation of something is described as "The action of limiting or placing a limit on something, constraint, restriction; an instance of this" (Stevenson 2015). Ignorance, as a limitation for the human agent, can affect different aspects of one's cognitive abilities, rationality, and perspective. Some of these effects prevent the ignorant (or ignoring agent) from doing something; some other effects enable her to do something else.

The preventing kind of ignorance includes different negative instantiations of it. One for all is

the type that agnotology studies: ignorance as the effect of cultural interferences and strategic manipulation of data. In some analyses, ignorance is even portrayed as a product that can be sold, bought, and distributed in accordance with someone's societal or economic interest. Eloquently, to motivate the use of the term "product" in relation to ignorance in their writings, authors who refer to the agnotologist school of thought often quote an internal memo of Brown & Williamson Tobacco Company that said "Doubt is our product" in reference to their campaign on the health risks of smoking. Misinformation and miscomprehension can depend on the efforts of some motivated groups of people. In this case, ignorance is an artificial limitations that affect the decision-making and problem-solving of directly or indirectly manipulated people.

Of course, there are also instances of ignorance that depend less on others' interference and more on one's condition as a limited cognitive agent. Ignoring something is, indeed, an action so natural that does not require any effort: in order to be informed, competent, or even an expert in some fields, we need to ignore other branches of knowledge. It is for this reason that the Traditional and the New view on ignorance are so focused on ignorance as lack of knowledge or true beliefs: they are the most common and recognizable instances. Discussing which kind of epistemic state would describe instances of ignorance is particularly important when, for example, we need to give standards to scientific research and knowledge. Even considering the fallible nature of these human endeavors, we need to keep searching for epistemic standards to give us reachable goals in our research.

Lastly, there are kinds of ignorance that do not prevent the agents to do or reason about something but favor them. For example, an instance of ignorance as a limitation that can create fruitful opportunities as much as problematic implications is the one that is used in common and extraordinary heuristics and ampliative reasoning. Sometimes we do not have enough information to choose an optimal strategy or to know without doubt an information: in these cases, guessing is not a random strategy. Most of the biases and

heuristics that inform our ordinary reasoning (from the bandwagon effect to the ad hominem reasoning) are fast and frugal strategies (as Gigerenzer and Goldstein (1996) named them) to arrive at a conclusion without all the necessary data. These strategies give us opportunities to act and collect new knowledge in short time and without needing complete information. Of course, they are not infallible procedures, but using them in the right context and for the right reasons can transform a situation of inaction into a discovering one. Studies on the peculiar ways that determine our use of these kinds of reasoning give us details about this uncovering of opportunities.

Moreover, almost the same kind of ignorance as a limitation is also involved in creativity, wonder, surprise, and acts of discovery (see ► ["Wonder"](#)). Ignorance is naturally involved in creative reasoning because creating something new implies not knowing beforehand what you are going to shape (Formica 2015; Magnani (2017), see also ► ["Creative Problem-Solving,"](#) ► ["Insight"](#)). Moreover, the act of creating something is powerfully connected to uncovering new affordances, possibilities, and unexpected chances: in turn, new chances and affordances bring out new questions and new aspects of one's ignorance.

Also, unexpected events can well connect the idea of ignorance to the possible. Indeed, surprise and wonder are productive ways to respond to new and unexpected events: intuitively, these responses help the agents face their ignorance and question their actual and potential knowledge. Agents, of course, can also react through negation, indifference, or rejection to the same new or unexpected event: in those cases, their ignorance is just preserved, and they miss out on the opportunity to learn and challenge what they know.

When a discovery is made, usually, the agents have faced and exploited their ignorance in a productive sense. In particular, serendipity, above all kinds of discovery, implies the reliance on our ignorance (as a limitation) as a trampoline to know more (Arfini 2019a; Copeland (Copeland 2017) see also ► ["Serendipity"](#)). Where we find new knowledge, our ignorance, as the horizon of our limitations, moves a little farther, challenging

us to find more, to know more. This can be much appreciated by quoting a marvellous anecdote that Firestein (2012, p. 57) recalled in his book on how ignorance drives science:

The eminent physicist Enrico Fermi told his students that an experiment that successfully proves a hypothesis is a measurement; one that doesn't is a discovery. A discovery, an uncovering, of new ignorance.

In sum, ignorance, approached as a general term, can represent the best and the worst of our epistemic goals and failures. In its analysis, the connection to the idea of the possible emerges as very direct: with knowledge comes possibility, and the understanding of ignorance directly fosters knowledge regarding human limits and limitations. So, the investigation of ignorance is naturally also the study of what are the possibilities that individuals and collectives have, whether it is to acknowledge their intrinsic limits or to push them to overcome their limitations in information, understanding, and competence. In brief, only by not ignoring ignorance, we can get a firm grip to what can we do with our actual and potential knowledge.

Illusion in Art

Baingio Pinna

Department of Biomedical Sciences, University of Sassari, Sassari, Italy

Abstract

Visual illusions behave like unexpected phenomena useful to create and sometimes to solve theoretical and epistemological issues and problems. They allow science to go further actual reality to explore the possible. Art itself is an illusion of human mind, primarily based and living within the domain of possibilities by continuously exploring possible worlds, possible selves, possible futures and theories on the basis of possible pasts. The unique combination of illusion and Art creates something special, attractive, astonishing, shocking, emergent, and, as shown in this entry, it involves even mathematics within the domain of possible.

Illusions, generally assumed as “mismatches/disagreements” between geometrical/physical and phenomenal domains, are attractive phenomena that manifest at least two basic phenomenal attributes, useful to understand their special role in Science and Art. They are called “illusoriness” and “realness.” The illusoriness describes the naive appearance of the notion of illusion expressing unreal, ambiguous, fallacious, misleading, and deceptive properties. Not all illusions appear illusory in both Art and Science. Some of them manifest an opposite sense of realness imprinting to stimuli and artworks a clear appearance of being true as actual objects, definitely not imaginary or hallucinatory. In this entry, illusoriness and realness are demonstrated to be related to a truth/falsehood antinomy, instilling

to Art a self-referential power that triggers interesting issues and paradoxes threatening the very existence of Art and, at the same time, speeding up its evolution. These issues are proved by means of thought experiments, corroborating within Art those already demonstrated in mathematics by Gödel, Turing, and Tarski. Their theorems about consistency, completeness, decision, and truth declared general statements analogous to those phenomenally achieved in our experiments. The results indicate intriguing connections between Mathematics and Art, suggesting that they are top performances of human thinking not very different and requiring deeper combined investigations and studies. On this matter, thanks to this entry, we propose new scientific hints and directions of research within the possible and the barely explored land placed between the science of illusions and Art and between Mathematics and Art.

Keywords

Visual perception · Visual illusion · Art · Paradox

Prelude

On the one hand, visual illusions behave like unexpected phenomena useful to create and sometimes to solve theoretical and epistemological issues and problems. As such, they allow science to go further actual reality to explore the possible.

On the other hand, Art itself is an illusion of human mind, primarily based and living within the domain of possibilities by continuously exploring possible worlds, possible selves, possible futures and theories on the basis of possible pasts (Glăveanu 2018).

This combination between illusion and Art allows exploration of changes, differences, new perspectives to understand and act within the world. Creativity emerging from illusions and Art puts these perspectives in dialogue, but also in contrast and, more importantly, in reflective and self-reflective mode. This further increases creativity (Glăveanu 2014, 2015, 2017) and expands

the domain and the notion possible within Art domain. It elicits awareness of differences, possibilities and, as such, favors self-consciousness of Art itself through its visual level and meta-level of perception vis-à-vis reality and the geometrical/physical domain.

The unique combination of illusion and Art also creates special, attractive, astonishing, shocking, emergent, and, as shown in this entry, it involves even mathematics within the domain of possible.

On Illusions

What is an illusion? What is illusory and what is real? What makes an illusion illusory? What makes an illusion real? These are the starting questions of this entry to be phenomenally investigated in this section.

Illusions are generally assumed as “mismatches/disagreements” between geometrical/physical and phenomenal domains (Robinson 1972; Coren and Girgus 1978; Gregory 2009; Vicario 2011; Pinna and Reeves 2017; Shapiro and Todorović 2017). They are sometimes taken as “deviations or errors” in perceiving what is real or what is known about the physical reality (Pinna and Reeves 2017; Todorovic 2016; Shapiro and Todorović 2017).

Within these views, illusions are useful to explore the complex epistemological fabric separating the physical and the phenomenal domains of perception and, thus, to build a psychophysical bridge between them. They are often used as tools to refute or demonstrate models and theories or designed to serve as limiting conditions or as *instantiae crucis* (crucial instances) aimed at testing general theoretical statements through their phenomenal attributes. Occasionally, they have become successful instances of *experimentum crucis*, according to which, if a given model is correct/incorrect, then a specific illusion is predicted and, thus, discovered as a phenomenological and logical corroboration/refutation of the model. Therefore, the discovery of an illusion does not depend on serendipity but on a logical reasoning based on a perceptual hypothesis or

model. This approach is even more common in visual arts, as shown in the next sections.

Within the ecological perspective (Gibson 1979), illusions are “picked up” when too much or too little information is present within the optical flow. On the contrary, according to the cognitive approach, illusions arise at the algorithmic level where errors, priors, or biases in the estimation of optic flow parameters emerge (Morgan 1996; Gregory 2009).

An extreme epistemological position suggests that all perceptions are illusory, but this means that if all is an illusion, nothing is (Noë 2002; Shapiro and Todorović 2017; Rose 2018). A final ultimate rebutting assumption indicates that the very concept of illusions is not necessary aimed to understand vision (cf. Braddick 1972, 2018; Shapiro and Todorović 2017).

These traditions and persisting debates reveal that illusions attract scientists by inspiring experiments, theories, questions, diatribes. These debates extended their boundaries to further complex domains like Art, where not only its products but Art itself can be considered as an illusion. This is the further argument of this entry discussed in details in the next section.

In spite of those hard debates, within and beyond the previous positions there is a general accepted definition of visual illusions according to which what is perceived does not match/agree with the stimulus pattern. In addition, there is a remarkable true/false assignment to illusions, mostly implicit and not fully studied, although phenomenally crucial for our purposes. Illusions are often accompanied by a prominent phenomenal attribute of “illusoriness,” which can be defined as a sense of strangeness, deception, singularity, mendacity, and oddity (Pinna 2013). This attribute has been frequently forgotten by scientists or confused with the notion of illusion itself. This might be responsible for the theoretical/epistemological diatribes and debates previously described.

The illusoriness can be clearly seen in Fig. 1, where a flashing green inside the purple annuli is perceived while moving the gaze across each element of the radial pattern. Actually, each element of the pattern is made up of a gray disc surrounded

by a purple annulus surrounded in its turn by black radial lines. Physically, there is not any flashing green color (Pinna et al. 2004).

The effect emerges not instantly and mostly while jumping with the gaze from one element to another (Pinna et al. 2004). In foveal vision, the inner grays lose part of their green effect. Once perceived, the phenomenon manifests its illusoriness, that is, the outcome is promptly seen as not real and illusory. Nothing similar can be printed on paper. The illusoriness is noted before any mismatch is revealed. It comes first, before the illusion is discovered. This shows the independence of the notions of illusion and illusoriness that likely belongs to different domains: cognitive, the former, and perceptual, the latter.

In Fig. 2, flashing purple colors are seen inside the green annuli. The resulting illusoriness is viewed analogously to those of the previous figure. The illusoriness is perceived as a further perceptual attribute of the illusion, that is, the illusion appears illusory. Again, the illusion is revealed by its immediate illusoriness without any need to check potential or actual mismatches/disagreements between the physical and the phenomenal domains.

In Fig. 3, luminous brightness enhancements emanate from the inside of the purple annuli

Illusion in Art, Fig. 1 Green flashing color within the purple annuli

Illusion in Art, Fig. 2 Purple flashing color within the green annuli

Illusion in Art, Fig. 3 Whiter than white effect within each purple annulus

(Pinna et al. 2003). The white inside each annulus, physically equal to the one of the background, is seen shining and brighter than the white background, that is, whiter than white. Again, the illusoriness pops up promptly and saliently.

Not all illusions are illusions in the same way. Not all illusions manifest phenomenal illusoriness. On the contrary, some true illusions are accompanied by a phenomenological attribute that looks opposite to illusoriness. Therefore, they do not appear illusory but real, true even after the revelation and the discovery of the mismatch. We call this phenomenological attribute “realness,” defined as a perceptual sense of being an actual thing with a true existence, that is, definitely not imaginary or hallucinatory (see also Reeves and Dresch-Langley 2017).

It is essential for a visual system to discriminate and appropriately perceive the phenomenal attributes of illusoriness and realness, of truth and falsehood of the outside world. This improves animal adaptation to the environment and enhances the evolutionary fitness. The complex symbiotic relation between preys and predators is based, among other factors, on the ability to discern and use illusoriness and realness in favor of their survival, to deceive, to attract, to mislead, and, therefore, to be successful in male

competition, mating, predation, and avoiding predation. Truth and falsehood, related to realness and illusoriness, are crucial components of real life used in different combinations, proportions, and purposes by all species and genders, animals, and plants. As proven in the next section, they are also crucial components of Art as used by artists of all times.

Figure 4 displays one example where strong realness is perceived regardless a “true” illusion. This is the watercolor illusion (Pinna 1987; Pinna et al. 2001; Werner et al. 2007). Star in the upper half and crosses in the lower half of the pattern clearly emerge filled with a light veil of orange tint. There is not illusoriness, nothing strange or deceptive. Apparently, what is perceived is exactly what is expected to be there. Nevertheless, there are only two juxtaposed wiggly contours, one purple and one orange, with reversed positions in the upper and lower patterns. In short, the two stimuli contain the same contours with inverted purple and orange colors. The inner light orange coloration is illusory.

Together with the coloration, there is another illusion without illusoriness that goes unnoticed at a first sight. Alike the coloration, this further outcome presents realness and this is likely the reason why it passes unnoticed. It is the salient

Illusion in Art, Fig. 4 Stars and crosses watercolored by a light veil of orange tint

volumetric figurality imparted by the two contours that seems like a light shading across the boundaries. Therefore, although crosses and stars are just before our eyes, respectively, in the upper and lower pattern, they are invisible due to the deep border ownership imparted by the reversed contrast of the juxtaposed contours. The resultant effect is an apparent gradient of dark and light coloration, such as a shading going from the border with the highest contrast, the purple contour, toward the center of each figure.

It is worthwhile highlighting that absence of illusoriness and perception of realness are definitely related, although they cannot be scientifically equated as one negation of the other. The lack of illusoriness is the absence of an attribute, and, as such, it is not a perceptual fact. Therefore, it is not necessarily related to the presence of the

realness, which is a genuine perception, that is, an actual phenomenal attribute.

To sum it up, the coloration (the inner light orange filling in) and the figural (i.e., stars or crosses) phenomena taken together express a salient realness attribute and an unlikely illusoriness, which emerges at most, albeit weakly, only *a posteriori* when the true physical conditions are revealed and the presence of only two adjacent contours is ascertained.

Yet about illusion with salient realness and poor illusoriness, in Fig. 5, it is hard to discriminate that the coloration of the inner edges of the two objects are physically the same (Pinna 2006), although they are actually seen truly different. When compared with the lower object, the upper one appears faded or discolored.

The examples illustrated in this section, beyond the specific effects, put into relief the phenomenal attributes of illusoriness and realness, crucial to understand the close connection between illusion and Art.

Indeed, Art in its history played with these two attributes, sometimes creating illusions of reality or making real what is just an illusion. Things in Art are not what they truly are, what they seem to be; however, they are often conceived more real than real, namely, with a realness attribute more intense than the one shown by real things. Moreover, Art is and always remains a construct of the mind that cannot be proved to have any other existence. As such it is a true illusion with a paradoxical high degree of realness even when its content is illusory.

Given these preliminary incipits, we are now ready to get inside the second basic side of this entry.

On Art

What is Art? Is Art a perceptual “object”? Is Art an illusion? What is real and what is illusory in Art? These preliminary questions lead us inside the complex issue of illusion and Art.

The common experience of Art in educated adults is comparable to the perception of a “real object.” However, Art is a perceptual “object”

Illusion in Art, Fig. 5 The coloration of the inner edges of the two objects is physically the same, although it appears discolored in the upper one

that, much more than others, is the product of the human mind and brain and, more importantly, it is not related to any specific element or attribute of the physical domain. On this matter, Gombrich (2000) emphasized the importance of “schemata,” according to which artists represent the outside world by learning from previous artists. As such, representations are created through stereotyped figures and methods. According to Gombrich, the perception of representational art requires the use of illusion, through which the viewer recognizes the subject within a painting as the one within the real world. In other words, in history of Art, artists have developed and studied the illusions that they experienced in order to render their paintings closer to the perception of “reality.”

There are further aspects and issues, useful to fully understand the specific characteristics of Art.

To better highlight them, a comparison with color and with the previous chromatic illusions might be useful.

Colors are naively assumed as physical components of objects, according to which they are perceived colored because “they are colored.” However, objects are not truly colored (see Werner et al. 2007). Colors are the final outcomes of a long chain of complex neural processes, starting with the spectral content of light, which is the basic physical domain. Photons are, then, absorbed by three different classes of cone photoreceptors in the retina, processed in different intermediate brain stations, and sent to specialized areas in the brain. The perception of colors comes up only at a final unknown link of the neural chain. This means that colors are illusions without illusoriness but with clear physical correlates that psychophysical methods can effectively measure.

Differently from colors, Art does not have any physical equivalent but it is a pure perceptual attribute that, despite all, turns out with high degree of realness likewise colors. Since Art is one of the few visual objects without a physical domain, immediate questions are: Is Art an emergent attribute? From what and from where does Art emerge?

In history of Art, some visual attributes conveyed and become expressions of Art. This is the case of *chiaroscuro* (Italian for light-dark): a technique aimed to create a gradient of contrast between light and shadow. Artists of the Italian Renaissance, like Raffaello (see Fig. 6), used a well-defined set of rules to apply light and shadow to a specific shape in order to create the illusion of space and depth.

The highlight marks and defines the point where the light is reflected orthogonally. It is usually the closest region to the light source, that is, the location where light is most concentrated. Highlight is commonly represented and perceived as a bright white on glossy or reflective surfaces. Moving away from the highlight, since light hits the object less directly, it exhibits a gradually darker value of gray. This is the shading. The shadow is the darkened area on the opposite side of the light source, and the core shadow is the

Illusion in Art,

Fig. 6 Raffaello Sanzio,
The marriage of the Virgin
(1504), Pinacoteca di Brera,
Milan

darkest center of the darkened region. The reflected light surface is the back edge of an object observed in a shadowed area. It is caused by the light reflected from another area or created by a secondary light source. The final component is the cast shadow that imparts an object a clear sense of space.

Leonardo da Vinci improved the effect elicited by chiaroscuro by creating soft and fuzzy transitions from light to dark between colors and tones, without lines or borders (see Fig. 7). He obtained a soft lighting/darkening effect called “Sfumato” (from Italian “toned down” or “evaporated like smoke”).

Chiaroscuro is a powerful technique to create a monocular depth illusion on a flat canvas similarly and even more intensely than the watercolor illusion of Fig. 4. As in the watercolor illusion, the resulting depth due to the chiaroscuro does not create any illusoriness. None of the observers of the previous paintings would think or say: “this is an illusion.” Indeed, the realness attribute is the true illusion, that is, the illusion of an illusion that shows up not illusory. Likewise Fig. 4, the realness is due to the realistic effect, therefore there is not any apparent strangeness, sense of deception, mendacity, or oddity. The depicted subjects appear quite

Illusion in Art, Fig. 7 Leonardo da Vinci, *The Virgin and Child with Saint Anne and Saint John the Baptist*, drawing (1510–1513), National Gallery, London

realistic, and this is exactly the illusion, an illusion of reality **tout court**.

This requires that by reducing the realness attribute, the illusoriness is expected to increase as shown in **The listening room** by René Magritte

(Fig. 8). Here, the questions is: Is this a gigantic apple placed in a normal room or a real apple in a tiny room? Both visual combinations are possible, although the most likely is the first one, possibly due to the prior assumption that the room is the

reference frame for the apple, which consequently looks gigantic.

Nevertheless, the point is that none of the two outcomes is an illusion, but both are possible scenarios. Differently from the chiaroscuro of Figs. 7 and 8, the illusoriness is now quite strong. The final outcome manifests a clear sense of strangeness and oddity, possibly because in the real world there are no gigantic apples. Therefore, the apple seems unrealistic. This indicates that the true illusion is the illusoriness.

It is worth noting that the realistic representation does not coincide with the realness attribute in such a way that what is unrealistic does not necessarily elicit illusoriness, as demonstrated in Fig. 9a.

Here, the direction of the illumination, depicting the shading of the sphere, is inconsistent with the one suggested by the location of the shadow. However, in spite of the unrealistic representation, the inconsistency and, thus, the illusoriness are hardly noticed and the realness is taken for granted (inconsistency blindness). This outcome is supported by the spatial effect imparted by the pseudo-shadow of the sphere, which looks as if floating above the background flat plane, elicited both by the shape and location of the shadow in relation to the sphere. Further

inconsistent and unrealistic shadow-shading combinations are illustrated in Figs. 9b with the respective control (Figs. 9c). These figures indicate that shadow and shading are independent attributes that do not require to be reciprocally consistent or realistic, but each of them defines a specific independent visual variable.

Figure 10 shows more dramatic effects of this inconsistency blindness. The questions are: What is wrong in these artworks? Which is the correct and which is the wrong artwork?

Taken together, all these examples denote that realness and illusoriness are two complementary antinomic attributes, according to which as one increases the other decreases.

There is a further important issue related to chiaroscuro, useful to deepen the connection between illusion and Art. It is well-known that the effects of depth and illumination imparted by chiaroscuro were abandoned or, rather, were totally abjured in Manet's *Le Dejeuner sur L'Herbe* ("the Luncheon on the Grass," Fig. 11), where the depicted subjects are depicted flat and illuminated by an impersonal and diffused light within an undefined perspective. Through Manet, a new meaning of Art comes to light. This points out that, in history of Art, a visual attribute was assumed as worthless when a new and, often,

Illusion in Art,

Illusion in Art, Fig. 9 Examples illustrating that the direction of the illumination, shown by the shading, can be inconsistent with the one suggested by the location of the shadow without being noticed and, thus, without illusoriness

Illusion in Art, Fig. 10 Examples of inconsistency blindness: what is wrong in these artworks? Which is the correct and which is the wrong artwork?

opposite property (e.g., volumetric vs. flat, real vs. unrealistic), replaced the previous one.

Moreover, assertion and negation of the same visual attributes marked the evolution of Art and, at the same time, advocated more intensely the question: what is Art?

Phenomenally, the forms of Art are considered like a self-contradictory representation or even like a succession of antinomic logically implied

attributes. The nature of these mutations is based on some kind of self-negation which favors the emergence of new properties and of new identities of Art. Paradoxically, the mutations of Art triggered its realness rather than its illusoriness. They might be the phenomenal engine letting Art to appear more and more as an independent object, a true perceptual object. Therefore, what is expected to destroy Art, due to its inner logical

Illusion in Art, Fig. 11 Édouard Manet, *The Luncheon on the Grass* (1863), Musée d'Orsay, Paris

antinomies, became, on the contrary, the foundation of its rebirth with an identity stronger than before. This is an interesting issue that needs to be deepened. The physiological mutations of Art state that, besides the physical domain, Art does not even have a clear ad univocal phenomenal domain. For instance, given the following famous paintings by well-known artists (see Fig. 12), basic and immediate questions are: What are the specific physical and phenomenological correlates of Art within this works? Where and what is Art within these paintings?

Even when Art is clearly recognized, the answer to these questions is hard or impossible. Art does not point out any clear phenomenal correlate and, vice versa, there is not any univocal visual attribute that identifies Art. It is even conceivable that different experts and scholars might locate Art on different attributes and meanings. Anyway, what remains constant in these paintings is the “idea” of Art and of something perceived as “artistic.” However, even this idea is undefined and undefinable inspiring a further question that requires to be answered: from what and where does the idea of Art pops up?

The main point is that, in spite of the undefined localization and identification, subjectivity, indefiniteness, and vagueness, Art is not conceived as illusory but real. It displays realness, although we know that it is not real. This implies a paradox that needs to be studied and solved.

To take a step in this direction, let us consider Malevich’s Suprematism, where Art is reduced to simple squares and/or circles (e.g., Fig. 13). More than in the previous paintings, the question “what and where is Art?” becomes compelling.

Paradoxically, these extreme reductions convey a stronger “idea” of Art, favoring its realness as a pure phenomenal object that does not need of a painting that shows specific abilities or techniques in the traditional sense. In short, the more extreme reduction of Art, the more maximum the phenomenal realness of the idea of Art. Suprematism and later movements freed Art from most of its canonical perceptual attributes and techniques becoming a visual meaning and an idea, which was further cleaned and highlighted in Conceptual Art.

What moved Art to take on the shape of a black square or circle on a white background? The

Illusion in Art, Fig. 12 Paintings by Francis Bacon, Willam de Kooning, Amedeo Modigliani, Egon Schiele, Gustav Klimt, Henri Matisse, Pablo Picasso, Sandro Botticelli, Johannes Vermeer. Where and what is Art within these paintings?

answer might be included in the following set of paradoxes. The square within Malevich Square is a trivial square; however, it is not “a square” because it is an artistic abstraction. Nevertheless, it is, *ipso facto*, a square since Art is reduced to a simple square in Suprematism. However, if Art can be reduced to a square, all the squares can be considered as Art, but if this is true it is also false, since all the squares are not Malevich Squares

and, as a consequence, they are not Art, but if they are not Art, then Art cannot be reduced to a square, thus, implying that Malevich Square is only a square and, as such, it can be Art since Art is brought to a square.

The circularity of the logic is self-evident. Each square is and is not a Malevich Square by following the same logic. Conversely, Malevich Square is and is not Art. Actually, everybody can create a

Illusion in Art,

Fig. 13 Kasimir Malevich, Black Square (1915) and black circle (1915), State Russian Museum, St. Petersburg

black square on a white background likewise Malevich; however, this square will never be a square in the meaning of Malevich Square. There is only one Malevich Square. All the others are only squares and not Malevich Squares.

These nested paradoxes might be responsible for the emergence of the idea of Art independently for its contents. They are likely behind what makes Art as a perceptual object and what elicits its realness, that is, the idea of Art as a meta-object. This occurs, even though, from a phenomenological point of view, all the squares can be Art in the sense of Malevich Square. Albeit all the squares are not Malevich Squares, they could be Malevich Squares.

The set of paradoxes can be simplified as follows: Malevich Square is a square that is not a square but not being a square it is a square. Moreover, in order to be artistic, the square must not be artistic by narrowing itself to a square; however, for these very reasons it is artistic (Pinna 2007, 2008).

These paradoxes are structurally reminiscent of Russel's paradox about the sets containing sets that are not members of themselves. Such paradoxes can be considered as interesting mechanisms of perceptual organization and reorganization of Art, triggering its continuous and unstoppable evolution.

Not only Malevich Square, but Art itself is a paradoxical phenomenal object according to which to be itself, that is, to be seen as such, it requires to switch and become something else. To be invariant as Art, namely, as a meta-object, it should vary in its instances, attributes, and creations. In short, Art

defines its identity if and only if it transforms itself. Therefore, to perceive and describe Art, we need to see and define its changes.

The origin of these paradoxes resides in the self-referential power of Art that comes from its independence from both physical and phenomenal domains. Art is then free to talk about itself and, as such, to create paradoxes different meanings of itself: Art both as an object and a meta-object. This interesting bipartition was clearly illustrated by Magritte's in *The Treachery of Images* and by the ready-made Duchamp's *Fountain* (Fig. 14).

In such a way, Art was able to talk about itself in terms of truth and falsehood, thus, evoking Eubulides paradox, stating "what I am saying now is a lie." This well-known paradox revealed the hard issue of self-reference in mathematics, as demonstrated by Gödel and Tarski.

Gödel, in his first incompleteness theorem, demonstrated that there is no consistent system of axioms able to prove all truths about arithmetic. Therefore, there will be statements on natural numbers that are true, although unprovable within the system. With his second theorem, he reveals that the system cannot demonstrate its own consistency.

The demonstration of the theorem, interesting for our purposes, is based on the following paradox: "This statement cannot be demonstrated." Therefore, if it can be proved, we obtain a falsehood, hence the system is incorrect. If it cannot be evinced, we have a truth, but now the system is incomplete. Therefore, the system is either incorrect or incomplete.

Illusion in Art,

Fig. 14 René Magritte, *The Treachery of Images*, Los Angeles County Museum of Art; Marcel Duchamp, *Fountain*, Lost artwork

Related to Gödel's theorems is Tarski's undefinability theorem, stating that no sufficiently rich language can represent its own semantics, therefore the metalanguage that is able to express the semantics of its object language must exceed that of the object language. It follows that theorems provable in the metalanguage cannot be demonstrated within the object language.

Thought Experiments on Illusions and Paradoxes of Art

Magritte and Duchamp artworks played with the same issues of mathematics by exploring and facing for the first time the sense of truth/falsehood as meta-logical categories of Art. But this is exactly what is phenomenally pointed out by illusoriness and realness. They are indeed the basic perceptual elements underlying the phenomenological game of Art based on the truth/falsehood antinomy. The double dichotomy truth/falsehood and illusoriness/realness builds the bridge between Art as object and Art as meta-object. This is a crucial point that asks for a more deep exploration from a logical and phenomenological perspective.

For this purpose, we can now perform a thought experiment similar to a mental model within an imaginary scenario. This procedure is useful to make clear our arguments, their implications and principles in an idealized context. This experiment can conceivably be also performed in a real lab. In history of science, thought experiments represented the most ancient pattern of mathematical proofs and, more recently, tools for Galileo's law, according to which falling objects

Questa non è ARTE

Illusion in Art, Fig. 15 *Conceptual art: "This is not Art" whose title is "This is Art". Is or is not this Art? The paradox of Art*

must fall at the same rate regardless of their masses, or means to prove the most famous Schrödinger's cat hypothesis.

The stimulus of our thought experiment is based on Conceptual art, according to which the idea or concept is the most and unique important aspect of the work. This is especially true when the concept is Art itself as shown in Fig. 15, where the sentence "Questa non è Arte" (Italian for "This is not Art") is our basic stimulus. (The thought experiment is imagined to be tested with Italian subjects.) This stimulus should be thought as if it is a true conceptual artwork made by a true artist. In addition, we have to imagine that title of this artwork is "Questa è Arte" ("This is Art").

Questa Non è ARTE

Against this background, we have an artistic content where the concept described is the most important predicate stating "this is not Art," namely, denying that this is Art, and a title that contradicts what is denied, thereby making the statement true. However, if it is true it is also false, since it states that this is not Art and vice versa. By extension, if one of the two parties is true, then it is at the same time false, since it is denied from its counterpart, but if it is false it is *ipso facto* true. What comes to light is a logically

self-contradictory double statement both true and false.

The logical antinomy remains unchanged if affirmation/denial of content and title is reversed, that is if the content becomes “This is Art” and the title “This is not Art.”

This thought experiment talks about Art and, at the same time, it can be Art itself, that is, a true artistic work, from which it talks about Art artistically through its paradoxes, not far from Magritte’s or Duchamp’s ways. By further continuing our thought experiment and imaging that it is true Art, we conceive again Art as an object and Art as a meta-object from an additional level of perception.

Nevertheless, as with Magritte’s and Duchamp’s artworks, we perceive also a clear sense of illusoriness vs. realness: realness of the inner logical antinomies and illusoriness of Art as a perceptual object and meta-object. Interestingly, the same perception pops up by reading Gödel’s and Tarski’s demonstrations in relation to the important strong implications for arithmetic.

We can now go beyond by making these perceptions even stronger with the following variation of the thought experiment. Readers are now invited to imagine the following new title “*Questa è Arte ma questo non è il titolo dell’opera*” (“This is Art but this is not the artwork title”). Under these conditions, another paradox within a paradox is revealed and this is related to the title that is and is not a title that talks about the content that talks about the concept of Art denying it. The chain of logical antinomies is now longer and the illusoriness vs. realness of Art stronger and stronger.

The illusoriness/realness dichotomy becomes more powerful if we think about the fact that everything we described above is based on a thought experiment. However, if we imagine that this is not a thought experiment but a true artwork, then everything is reversed in terms of illusoriness/realness.

The next immediate question is then: Is this Art or just a word game? The answer could be that it is both Art and a word game and that all the previous conditions are possible, but this is exactly the illusion of Art. This play of visual/cognitive levels

and meta-levels is based on the fact that Art is one of the most self-referential expressions and languages of the human mind, not different from mathematics.

There is a further interesting point to be considered. The exercise of logic with Conceptual art can be repeated at a small scale with every kind of painting (e.g., Raffaello’s *The marriage of the Virgin*), where signifier and signified can be considered as the two sides of the painted signs, where the signifier is the image represented (illusoriness) and the signified is the concept (realness), namely, the idea of what is represented (cf. de Saussure 1959). This depends again on the self-referential power of Art that necessarily leads to the previous paradoxes. It follows that also Conceptual Art can be considered as a natural consequence of the self-referential power of Art related to the illusoriness/realness dichotomy based on the truth/falsehood antinomy.

A final intriguing issue, coming to the fore as a final step of our thought experiment, is based on the following decision question: Is there a yes-no answer to the question “is this Art?”? In other words, is there a decision procedure, criterion, or some sort of algorithm for this basic question? Is there an effective method to determine the existence of Art within a painting or to decide its membership and belongingness to the set of Art?

This issue is reminiscent of Turing’s halting problem and the answer to this problem in Art is exactly the same, that is, negative, for the reasons highlighted above on the basis of the illusoriness/realness dichotomy.

A further effective way to prove phenomenally the decision problem is illustrated in several variations of the artwork of Fig. 15 (see Fig. 16). We can imagine again a thought experiment, where the questions related to these variations are: do they belong to Art? Which of them is more artistic?

As a matter of fact, all the variations may or may not belong to Art according to a criterion or a method to decide it. If we choose an aesthetic criterion (e.g., the most strange, irregular, beautiful) to decide what is Art among these writings, then we are betraying Conceptual Art, therefore none of them is Art within this meaning. If we choose a Conceptual criterion, then all of them

Illusion in Art,
Fig. 16 Variations of the
 artwork of Fig. 15

could be Art, but this implies that each of them is Art and, thus, that there is not any effective method to decide what is Art.

This becomes even more clear if we try to answer the following questions: What if in our thought experiment we imagine that only one of the variations of Fig. 16 is Art? What if none of them is Art? Why are they not Art? These questions lead straight to the decision problem where truth/falsehood and illusriness/realness are the primary players. Given these questions, it is impossible to think to a general criterion or an algorithm that always leads to a correct yes-or-no outcome. More generally, defining what Art is or is not is an undecidable problem.

To conclude this section, it is noteworthy that the inner auto-referential paradoxical nature and the problems of consistency, completeness, and decision, belonging to both Art and formal systems like arithmetic, denote and prove strong important connections between the two domains, likely distant in appearance only and waiting to be fully explored and studied.

Conclusions

In this entry we have shown that illusions, generally assumed as “deviations/errors or mismatches/disagreements” between geometrical/physical and phenomenal domains, are intriguing phenomena for both scientists and artists

based on two crucial phenomenal attributes called “illusriness” and “realness.” The illusriness is related to the naive appearance of the notion of illusion expressing unreal, ambiguous, fallacious, misleading, and deceptive attributes. As stated in the previous sections, in both Science and Art, not all illusions appear illusory, but some of them manifest an opposite attribute. This is the realness, which is only apparently absence or negation of illusriness. As a perceptual attribute, it imprints to stimuli and artworks a clear sense of being true as an actual thing with a real existence, definitely not imaginary or hallucinatory.

Illusriness and realness are shown to be related to the truth/falsehood antinomy, crucial for the evolution of Art and for its self-referential power, responsible for triggering interesting paradoxes and issues threatening the very existence of Art and, at the same time, speeding up its evolution by generating levels and meta-levels of itself. This was clearly exemplified by the astonishing expressions and developments of Art during the last century.

The basic paradoxes and issues, resulting from the thought experiments proposed in this entry, are strongly related to those already studied in mathematics by Gödel, Turing, and Tarski, whose theorems about consistency, completeness, decision, and truth demonstrated conclusive outcomes about formal systems similar to those phenomenally achieved in our experiments

about Art. These common outcomes suggest important connections between Mathematics and Art, according to which they are two high level form of thinking, likely distant in appearance only and requiring to be more deeply investigated and studied. In this regard, through this entry, we have provided new clues and shown new directions of research within the possible and the still unexplored scientific land bridging Mathematics to Art and placed between the science of illusions and Art.

Finally, the special combination of illusion and Art elicits the exploration of new words, selves, theories, and futures, starting from paradoxes that stimulate the emergence of languages and meta-languages, objects and meta-objects, and, possibly, consciousness and self-consciousness within the large domain of possible.

Illusion in Perception

Baingio Pinna

Department of Biomedical Sciences, University of Sassari, Sassari, Italy

Abstract

Illusions, similarly to phenomena, paradoxes, and unexpected outcomes, play a key role in science since they often represent, create or anticipate theoretical and epistemological problems. They trigger “as if,” “what if,” and “if only” thinking processes that are fundamental elements within scientific reasoning. The common denominator between these key points and their illusions is to go beyond the actual reality to explore the possible. In short, illusions represent the surprising discover activating the sense of possibility and the incipit to start the exploration of the large no-man land where the notion of possible grows.

Within modern vision science, illusions are attractive phenomena that play an important role as tools to explore vision under limiting psychophysical conditions. Illusions manifest at least two issues that challenge scientists. The first issue is related to the main definition of illusion, and it is based on the complexity of the mismatch between the two geometrical/physical and phenomenal domains. Basic questions are: What is geometrical/physical and what is phenomenal? What is the meaning of the mismatch/disagreement in between these two domains that are so different both scientifically and epistemologically? The second issue concerns the two different meanings of the term “illusion,” respectively related (i) to the logical demonstration of the illusion through the mismatch between domains and

(ii) to the phenomenal illusoriness, i.e., the perception of something having the nature of an illusion, something unreal, ambiguous, fallacious, and deceptive.

This entry begins with the most accepted definition of illusion and with a short description of the main scientific historical controversies on the meaning of illusion and on their place in science. Then, by means of 11 figures, the complexity and importance of illusions in vision science are demonstrated both logically and phenomenally. The starting figure is a simple and apparently not illusory condition of perceptual grouping, which gradually reveals its hidden illusions that increasingly manifest their phenomenal illusoriness. The conclusion of the entry is that the perception of illusion vs. illusoriness can be considered as a further challenge for scientists and it is useful to shed a new light within the biological meanings of visual perception and within the scientific no-man land between “sensory” and “cognitive” processes which are not fully explored yet.

Illusion: Definition, History, Controversies

Illusions, similarly to phenomena, paradoxes, and unexpected outcomes, play a key role in science since they often represent, create or anticipate theoretical and epistemological problems. They trigger “as if,” “what if,” and “if only” thinking processes that are fundamental elements within scientific reasoning (Glăveanu 2018). The common denominator between these key points and the illusions is to go beyond the actual reality to explore the possible. In short, illusions represent the surprising discover activating the sense of possibility and the incipit to start the exploration of the large no-man land where the notion of possible grows.

Illusions are historically related to a “mismatch/disagreement” between the geometrical/

physical and the phenomenal domains (Robinson 1972; Coren and Girgus 1978; Gregory 2009; Vicario 2011; Pinna and Reeves 2017; Shapiro and Todorović 2017). This definition of “visual illusion” is commonly assumed and accepted, both explicitly and implicitly, when an illusory phenomenon is discovered and first brought to the attention of the scientific community. This entails that, illusions, as results of cognitive processes, are concerned first and foremost with the dichotomy between the possible and the actual or the real. It doesn’t mean that the possible is outside of reality, different or opposed to it (see next sections).

Other terms have also been used to define illusions, though with very similar meaning. These are “deviations” or “errors” in the perception of physical reality or “discrepancies” between perceptions and our knowledge of the physical reality (Pinna and Reeves 2017; Todorović 2016; Shapiro and Todorović 2017). Moreover, illusions have been suggested as the results of processing too much or too little information (Gibson 1979) or to arise at the algorithmic level with errors/biases in the estimation of optic flow parameters (Morgan 1996; Gregory 2009). These approaches were further extended to consider all perceptions as illusory and, consequently, either all is an illusion or nothing is (Noë 2002; Shapiro and Todorović 2017; Rose 2018). Finally, a harsh controversy, developed several times in the history of perception, suggests that the very concept of illusions is scientifically unnecessary to understand both vision and even the same phenomena perceived as illusions (see Braddick 1972, 2018; Shapiro and Todorović 2017).

Beyond and regardless of controversies and alternative approaches, the most accepted general idea of visual illusion is related to what appears to be present within the stimulus pattern that does not match/agree with what is perceived. This means that the necessary condition to perceive and demonstrate an illusion is the discovery of a clear inconsistency between these domains.

It is worth noting that a sense of vivid surprise and amazement is usually accompanied to the perception of illusions. This is what makes illusions attractive to both scholars and naive

observers. This is a phenomenological attribute of visual illusions, the illusoriness, never studied before although it is worths deep scientific attention.

In spite of the apparent simplicity and unambiguous uniqueness of the previous definition, after a closer inspection, it turns out to be intrinsically ambiguous both on the domains involved and on their logical and phenomenological relationship. Useful questions, to start a productive scientific argument on this matter, are the following: What is physical and what is phenomenal? What is a mismatch/disagreement in between two domains actually so different both scientifically and epistemologically?

Illusions together with the notion of possible imply the rethinking of the scientific status quo and the exploration of possible worlds and possible scientific and epistemological futures. The meaning of these questions and of their related issues are logically and phenomenally discussed in the next sections which go inside the complexity of the concepts of illusion and illusoriness (see Pinna 2013).

Illusory Deformations from Grouping

Going back to the main definition of illusion, i.e., of what appears to be present within the stimulus pattern that does not match/agree with what is perceived,” a basic significant issue emerges. Logically speaking, the content of the statement is related to the comparison between two perceptions, i.e., what appears to be present in the stimulus pattern and what is perceived. The physical/geometrical domain is something to be perceived thanks to some kind of direct or indirect measurement able to see its mismatch with the phenomenal codomain. They are indeed two perceptions or two different ways of perceiving the same object. As a matter of fact, to perceive a mismatch, it is tautologically necessary to perceive it, i.e., to compare the two perceived outcomes and by way of the comparison to perceive the related mismatch. Although this issue can, at a first sight, be considered tautological, too abstract or left-brained, it can become scientifically

important in the light of the next figures and of the notion of illusoriness that they gradually and increasingly reveal.

Figure 1 shows five simple conditions made up of black and white dots placed on the corners of a vertical/horizontal lattice. Via very similar stimuli, Wertheimer (1922, 1923), first, studied the problem of perceptual organization in terms of grouping. The main questions he answered are: how do elements in the visual field “go together” to form an integrated percept? How do individual elements create larger wholes? To answer these questions, he explored and discovered the following well-known grouping principles: proximity, similarity, good continuation, closure, symmetry, convexity, *Prägnanz*, past experience, common fate, and parallelism. Quite simply, the similarity principle states that, all else being equal, the most similar elements are grouped together.

In Fig. 1, the similarity principle in terms of reversed contrast (contrast polarity) groups the dots in columns (Fig. 1a), rows (Fig. 1b), or obliquely (Figs. 1c-d) against the proximity

principle, since the amplitude of diagonals is longer than the horizontal/vertical ones. In Figs. 1e-f, similarity creates two blobs, made up of white/black dots, emerging as figures from the background of a squared lattice of black/white elements. This outcome demonstrates the seamless and close connection between figure-ground segregation (Rubin 1921) and grouping: the principles working in one domain operate also in the other domain, creating phenomenal *Gestalten* (pl. of Gestalt: form, shape, configuration, structure, arrangement, organization, figure).

Going back to the main definition of illusion, under the conditions of Fig. 1, what appears to be present within the stimulus pattern apparently matches and agrees with what is perceived, therefore there is no illusion at all. Both the mismatch and the property of being illusory are not perceived. Indeed, this kind of results were never included within any catalog of illusion but they are generally assumed as good examples of phenomenal grouping. In Layman’s terms, the grouping is not an illusion and it does not appear illusory.

Illusion in Perception, Fig. 1 The similarity principle: all else being equal, the most similar elements are grouped together creating columns, rows, oblique arrangements, and blobs

Illusion in Perception, Fig. 2 The whole geometrical squares, made up of dots and square checks, appear as horizontal or vertical rectangles on the basis of their horizontal or vertical grouping due to the similarity or proximity principles

In spite of this trivial conclusion, at closer observation, this first impression can be questioned. By carefully comparing Fig. 1a, b, the grouping in columns and rows slightly deforms in opposite directions the two whole geometrical square shapes of dots. The grouping in columns induces an upwards elongation of the whole square that appears like a vertical rectangle, while the grouping in rows favors the perception of a wide horizontal rectangle. These phenomena are more easily noticeable in Fig. 2 (first row), where two portions of Fig. 1a, b, made up of four by four dots with opposite contrast polarity, are illustrated.

Whole horizontal rectangles are clearly perceived when the grouping is horizontal, and elongated vertical rectangle, when the grouping is vertical. Similarly, the four whole geometrical squares (second row), made up of square checks, appear as horizontal or vertical rectangles on the basis of their horizontal or vertical grouping due to similarity and proximity principles. The same

kind of shape distortions is perceived in the third row, where the squares of the second row are now replaced with diamonds.

The question is now: are these conditions visual illusions? In terms of the main definition, the answer should be in the affirmative, and the theoretical conclusion has to be that grouping principles influence not only the way elements in the visual field “go together” to form an integrated, holistic percept, as suggested by Gestalt Psychologists, but also they affect the whole shape perception. It is worth noting that not only the whole square shape is affected by the similarity principle, but also the inner small squares and diamonds are deformed in the same way. This outcome is just noticeable (for further stronger results see Pinna 2010a, b, 2012).

The connection between grouping and illusions becomes stronger and stronger by following the rational and the phenomenal outcomes of the next figures.

The rectangle illusion perceived in the previous figures is related to a well-known illusion, Helmholtz's square (Fig. 3), where a whole square appears wider like a horizontal rectangle when it is filled with vertical lines and higher, like a vertical rectangle, when filled with horizontal lines (Helmholtz von 1866; Da Pos and Zambianchi 1996).

By comparing the rectangle illusion and the Helmholtz's square, what immediately struck is the opposite direction of the illusory effects, although the same results apparently must be expected. An unsolvable antinomy seems to emerge from the two illusions. More specifically, since a square made up of vertical lines (columns) appears wider and larger than an identical square built with horizontal lines (rows), why does a square composed of dots grouped in columns appears, on the contrary, taller and narrower than an identical pattern where the elements are

horizontally grouped in rows? Apparently, the explanation of one effect (i.e., Helmholtz's square) leaves the other unexplained and vice versa. Therefore one phenomenon is a counterexample of the other.

What is clear is that both visual phenomena are illusions. Moreover, what is now emerging is the visual property that was invisible when Fig. 1 was first described. This is the illusoriness, namely, the attribute of something having the nature of an illusion. The illusoriness is here related to the mismatch between the geometry of the whole shape and its perception, but also to the apparent antinomy between the rectangle illusion and the Helmholtz's square. The strength of this attribute will increase in the next figures.

The question is now: can the two opposite phenomena be predicted by the same explanation? Apparently, the answer is negative. However, deeper phenomenological analysis on the

Illusion in Perception, Fig. 3 Two examples of Helmholtz's square illusion showing the widening of the square made up of vertical lines and its lengthening when the lines are horizontal

grouping principles shows that, under our conditions, there are at least two sources of perceptual organization. One is local and it belongs to each element component (dot or line-segment), the other is global and it is related to the direction of the grouping/ juxtaposition of elements. More in details, the local directional organization of the lines within Helmholtz's squares is the one that belongs to each line, i.e., respectively, vertical or horizontal. However, their global directional organization, imparted by grouping, are the opposite. It means that the vertical lines are distributed horizontally, while the horizontal ones, vertically. But this is exactly what happens also with the dots of Fig. 2, where their directional organization is the same as those in Helmholtz's squares, i.e., the dots are distributed horizontally or vertically similarly to the lines of the Helmholtz's squares. This implies that the only responsible of the whole shape, either when the elements are lines or dots, is the global grouping. Therefore, Helmholtz's square with vertical lines is perceived wider because of the horizontal distribution of lines, i.e., similarly to the horizontal grouping of dots of the rectangle illusion, while, conversely, the square with horizontal lines appears higher because of the vertical grouping of lines that is the same direction of the vertical grouping. In conclusion, the illusory deformation of the whole geometrical square follows the same directional organization imparted by the grouping of the inner elements (both lines or dots).

If this is true, then the effects of both the illusion of rectangle and Helmholtz's square can be significantly increased or, conversely, reduced by playing with the grouping principle of similarity, which appears to be the only responsible for the emergence of these illusions.

In the first row of Fig. 4, the outcomes of Helmholtz's square illusion are amplified, since two horizontal (left) and vertical (right) groupings operate synergistically. On the contrary, the illusions are drastically minimized or totally annulled in the second row, because the two groupings are now pitted one against the other.

Illusory shapes from grouping

The previous results connect perceptual grouping with visual illusions and evoke the basic questions above mentioned: What is physical and what is phenomenal? What is a mismatch/disagreement between the two domains? Our outcomes might represent a preliminary answer to both questions by showing the difference between the two domains, namely, square vs. rectangle, and by demonstrating the disagreement between geometrical squares and the perceived rectangle illusions. However, this immediate deduction becomes more complex in light of the following phenomena that further expand the scientific meaning of the grouping principles.

In Fig. 5, the grouping by similarity among the square checks induces directional organizations along with the whole vertical diagonals (first row) or along the oblique sides (second row) of the whole pattern of check elements, thus, highlighting, respectively, sides and angles of the single checks, and angles and sides of the whole group of checks.

In the first pattern of the first row, square checks are geometrically arranged in a large diamond. Perceptually, the vertical organization along the diagonals/angles of the whole diamond and on the sides of the checks, imparted by the similarity principle, accentuates the perception of global diamond shape and favors the perception of a square in every single check. In other terms, the single squares are seen as squares and the global diamond is perceived as a large diamond.

Conversely, in the second pattern of the first row, the single diamonds are perceived as "diamonds" and the whole diamond pattern is viewed as a "diamond." These results apparently do not reveal any unexpected effect. However, by considering them as controls, the main illusory phenomena are clearly recognized in the next two patterns of Fig. 5.

In the first pattern of the second row, the whole diamond is observed as a rotated square and the single square checks are seen as diamonds. Conversely, in the second pattern, both the whole diamond and the single diamond checks are perceived as rotated squares. By focusing only on the

Illusion in Perception, Fig. 4 The size effect of Helmholtz's squares can be strengthened (first row) or weakened (second row) by pitting the sources of

directional organization, imparted by grouping principles, synergistically or one against the other

single checks of the second row, squares are noted as diamonds (left) and diamonds are distinguished as rotated squares.

These results are corroborated and emphasized by comparing these patterns of stimuli with the controls illustrated in Fig. 6.

Phenomenally (see Pinna 2010a, b), rotated squares and diamonds, due to their orientation determined by the similarity principle, reveal the two opposite attributes of the square check: the "sidedness," namely, the appearance of being flat and stable, and the "pointedness," i.e., the property of being sharp and unstable. Although these attributes can be geometrically considered symmetrical in strength, phenomenally, sidedness is much stronger than pointedness within the rotated square, while pointedness comes up more clearly within the diamond. Fig. 5 demonstrates that the salience of one of these two attributes can be easily accentuated by the similarity principle (see also Pinna 2010a, b, 2012, 2015).

This assumes that a rotated square and a diamond are phenomenally two different shapes, not because they have two different names, but because they exhibit one of the two phenomenal

attributes, pointedness and sidedness, more strongly than the other. Therefore, they have different names since they show two different and opposite properties.

These results further increase the perception of illusoriness and extend the meaning of the similarity principle, considered in the beginning only as a principle of grouping without illusory effects. In the next section, the role of similarity as a generator of visual illusions and illusoriness is further explored.

Illusory Motion from Grouping

In Fig. 1e–f, two conditions in between figure-ground segregation and grouping were described. Again, this is not the full phenomenological story. In fact, a closer inspection points out an illusory dynamic and instability of the inner components that slightly appear as floating behind or in front of the surrounding elements. This effect, just noticeable, can be improved by increasing the similarity/dissimilarity between the two inner and surrounding regions as illustrated in Fig. 7.

Illusion in Perception, Fig. 5 Squares and diamonds perceived as squares and diamonds (first row); squares perceived as diamonds and diamond perceived as rotated squares (second row)

Illusion in Perception, Fig. 6 Controls for Fig. 5

Illusion in Perception, Fig. 7 Dissimilarity among elements and regions induces floating and sliding motion

Here sharp depth segregation is perceived with the inner regions as placed in front of the large square shape (on the left) or behind two holes (on the right). While the stimuli are irregularly weaved, illusory floating and sliding motions are perceived.

This illusory motion in depth is stronger in Fig. 8. The two central square frames amplifies the figure-ground segregation and the dissimilarity between the inner and outer regions of the two figures.

A strong illusoriness, due to the impression of instability and floating effect of the filled circles without any clear direction of motion, is represented in Fig. 9.

Another motion effect, imparted by the similarity/dissimilarity and grouping principles, is shown in Fig. 10. Under these conditions, the geometrical diamonds (squares rotated of 45°) are recognized as illusory elongated rectangles rotated in opposite directions in alternated columns. This is due to the directional accentuation elicited by the white dots placed on the opposite sides of each diamond, thus highlighting the sidedness attribute.

More importantly, Fig. 10 illustrates a clear sliding motion induced on the columns of illusory rectangles. This result turns out very easily when

the gaze follows the tip of a pen moving vertically or horizontally across the check of the pattern but with attention and peripheral vision focused on the surrounding elements. While the pen is moving vertically the sliding motion is perceived horizontally and, vice versa, when the pen moves horizontally the illusory motion occurs vertically.

These results denote that, in Fig. 10, there are at least three different kinds of illusions, all consistent with the effect generated by similarity/dissimilarity among element components. They are: (i) deformations of the square shapes that appear elongated like rectangles in the directions of the white dots; (ii) checks observed as rotated rectangles, not as diamonds although geometrically they are diamonds; (iii) sliding motion in a direction opposite to the real motion.

The apparent motion is further strengthened in Fig. 11 by chromatically differentiating the columns composed of ellipses oriented in orthogonal directions.

Conclusions: Illusion and Illusoriness

In this entry, Gestalt principles of grouping were demonstrated to induce strong visual illusions. As

Illusion in Perception, Fig. 8 A sharper dissimilarity and figure-ground segregation among regions elicit a stronger illusion of floating and sliding motion

Illusion in Perception, Fig. 9 Illusoriness due to the appearance of instability and floating motion of the filled circles without any clear direction of motion

Illusion in Perception, Fig. 10 A strong sliding motion illusion in a direction perpendicular to the true motion

a matter of fact, these principles do not only group, but, by putting together similar elements and, at the same time, separating them from others, highlight directions, shape components, orientations, and create compelling visual illusions of shape and motion. This suggests that illusions are the results of processes of perceptual organization and, as a consequence, that they can be used as scientific tools to better understand the complex dynamics of visual organization beyond the classical Gestalt principles of grouping and

figure-ground segregation, which, under our conditions, have revealed clear scientific and theoretical limits. Especially by means of the last figures, it was also shown the intense sense of illusoriness, perceived in its full phenomenal meaning of something having the nature of an illusion, something unreal, ambiguous, fallacious, deceptive, false, fictitious, or misleading. These results, when compared with the ones of Fig. 1, indicates that the demonstration of an

Illusion in Perception, Fig. 11 The apparent motion is enhanced by chromatically differentiating the columns of orthogonal ellipses

illusion and the visual attribute of being illusory are two different issues. Even when the illusion is clearly ascertained, e.g., in Figs. 1a, b, the illusoriness does not necessarily pop out but it can remain weak or totally absent. Conversely, the illusoriness can come out at a first sight much earlier the discovery and the demonstration of the illusion (e.g., Fig. 11).

The illusoriness is perceived with different degrees of vividness, sometimes weakly, in other cases very strongly and independently from the mismatch between domains. Moreover, going from Figs. 1–2, the illusoriness arises as a consequence of cognitive bridge between different domains instead of a genuine perceptual process as in Fig. 11. Since the illusoriness of Fig. 1 is sometimes weak as a result of a logic process of comparison than a vivid outcome of a visual attribute, its vividness can be considered as a tool to measure the amplitude of the “visual” and “cognitive” processes involved and of the gap between them. On the contrary, in Fig. 11, the illusoriness is strongly noted before the mismatch is revealed.

Here, the illusoriness comes first, before the illusion, not discovered yet. This implies the independence of the notions of illusion and illusoriness that likely belong to different domains: cognitive, the former, and perceptual, the latter.

On the basis of the previous outcomes, the perception of illusion vs. illusoriness can be considered as a further and future possible challenge for vision scientists useful to shed new insights within the biological meanings of visual perception and within the no-man land between “sensory” and “cognitive” processes not fully explored yet.

In conclusions, the notion of possible triggered by visual illusions through “as if,” “what if,” and “if only” questions elicit new fundamental questions, issues and dichotomies useful to explore further ideas, concepts and scientific theories beyond the actual reality and toward the possible futures.

Imagery

Alessandro Antonietti

Department of Psychology, Catholic University of the Sacred Heart, Milan, Italy

Abstract

Imagery, namely, the mental representation of objects and scenes which preserve some features of the corresponding sensorial experience, can play a role in inducing people to figure out possible situations. More precisely, thanks to its intrinsic characteristics, imagery allows people to generate and manipulate flexible representations through holistic thinking strategies to enhance performance in problem-solving and creative tasks. However, individual differences in the ability to manage imagery are reported. This stresses the need to train individuals to use imagery efficiently in order to lead them to imagine alternative states of the world.

Keywords

Creativity · Imagination · Individual differences · Mental representation · Problem-solving · Transformation · Visualization

Introduction

The term “imagery” refers to the complex of mental representations, which keep some aspects of the corresponding sensory experience (and this gives reason of their relation to perception) even though they are generated in the absence of the relevant physical stimulus (and this explains why they are included in the thinking processes) (Kosslyn 1994). In the framework of such a general definition, visual imagery concerns the picture we may have in our mind when we, for instance, remember the aspect of the façade of the house where we live even if we are not actually in front of it (it is argued that in a situation like

that we are employed our “mind’s eye”). A case of auditory imagery is when we are “hearing” in our mind how the national anthem sounds like if it would be played by a violin but not by trumpets as it usually occurs. In the same way, we can generate olfactory, gustative, tactile, and somatosensorial or kinesthetic mental images.

According to Kosslyn (1983), mental images play a role in cognitive processing because they can be meant both as symbolization and simulation tools. As *symbolization* tools, mental images stand for objects or concrete events, which are replaced by signs. As *simulation* tools, mental images allow people to form an internal representation that keeps an analogical correspondence with the external world. More precisely, we can distinguish two forms of simulation: the simulation of what is occurring in the reality or occurred in the past and the simulation of what might occur. In the first case, mental images *reproduce* the actual world (as in the example of the mental visualization of the house’s façade). In the second case, they *anticipate* (see ► “Anticipation”) or *create* possible worlds (as in the example of the auditory image reported before: even though the anthem has been never played by a violin, this may happen in the future). In this sense, imagery is linked to the topic of the “possible.”

Why Imagery Contributes to the “Possible”

Several biographical and autobiographical reports suggest that mental images led scientists to figure out how reality might be conceived by discovering alternative possibilities to understand it (Shepard 1978). For instance, Albert Einstein, at the age of 16, in a ► “Thought Experiments” imagined himself traveling at the speed of light sitting on the end of a light beam with a mirror in front of him. In this mental image, the observer could not ever see the image of the traveler. The light and the mirror, in fact, were traveling in the same direction and at the same speed, so that the mirror was always a little ahead of the beam and the traveler could not reach the mirror and could not see his reflection. From this mental image, Einstein concluded that there could be no observer

(i.e., no body) that can reach or exceed the speed of light. In this way, he went beyond the assumption, shared by past and contemporary physicists, that an object could achieve any speed, given a sufficient enough acceleration, and this change in comprehension was one of the bases of the subsequent theory of relativity (Bohm 1980). Also, inventors took benefit from mental images to devise instruments which were not still existing. As an example, Nikola Tesla (1956) designed neon lights and self-starting engines by visualizing the mechanical models of the prototype of these devices that he ran in his mind for several weeks in order to check if they might work (see ► “Innovation”).

Suggestions coming from this genre of anecdotes have been confirmed by empirical research (Forisha 1978; LeBoutillier and Marks 2003; Palmiero et al. 2016; Roskos-Ewoldsen et al. 1992). High correlations were found between the use and control of mental images and ► “Future Problem Solving” abilities (Van Garderen 2016), as well as ► “Divergent Thinking” (Forisha 1981). Imagery promotes creative (see ► “Creativity”) language skills linked to poetry writing (Wilson 2007). The spontaneous use of imagery in pre-school playing behavior is predictive of more creative skills in older children and adults (Singer and Singer 2006). The link between imagery and creativity also appears to be in the opposite direction: creativity induces a more frequent and complex use of mental imagery (Saracho 2002).

Why can imagery help people to conceive new views of the reality, not currently recognized or accepted (as in the case of philosophy and scientific theorizing), to figure out or predict what might occur in the reality (as in the case of discovery and ideation of experiments), and to create something which was not still existing (as in the case of the production technological and artistic artifacts)?

Imagery could be relevant to the ideation of the possible since mental images are not “photocopies” of objects or scenes because they do not correspond point-by-point to the original stimulus. They are mentally organized in structural terms, i.e., by grouping elements in such a way

as to form meaningful units. Hence, they allow people to quickly extrapolate the most important elements from the representation, thus producing a schematization in which the essential features are highlighted. This makes it easy to identify what might ► [“Social Change”](#) or be changed in a situation so as to achieve a different outcome (Antonietti 1991).

In addition, mental images can be analyzed and transformed in a holistic manner, i.e., by acting on all their parts simultaneously but not part-by-part. In this way, they favor the processing of information because, by allowing several operations to be carried out simultaneously, they reduce the cognitive load and, by permitting people to process information in parallel, i.e., in such a way that various aspects are taken into account simultaneously, they speed up the process (Kaufmann 1981). The possibility of taking several aspects into account simultaneously is particularly useful when it comes to operating in ambiguity and ► [“Uncertainty”](#), i.e., in situations in which it is not advisable to choose one direction straight away and exclude the others, but it is better to consider all possible paths since we have no sure clues as to whether one or the other is preferable (Kaufmann 1985).

A further reason is that mental images can be easily manipulated because they are extremely flexible representations. They also allow one to imagine transformations that would be impossible to implement physically and to move from one situation to another or make sudden associations, even between very distant elements. All these processes facilitate the conceiving of different states of the world.

On the basis of these arguments, Kaufmann (1985) introduced the notion of “level of programming” as a major determinant of the functional usefulness of imagery in problem-solving. A problem is programmed if people possess one or more procedures to handle it and, consequently, they do not need further information to proceed. A problem is nonprogrammed when it appears unstructured and/or requires that new information is acquired. When, in a nonprogrammed task, abstract or verbal processing leads to a block, imagery may yield a rearrangement of the problem

elements so that reasoning can go on productively. Visualization may result useful also in situations demanding novel or different approaches rather than routinized strategies. This author claimed that the relative importance of imagery in the solution process is high with unfamiliar problem and decreases with increasing problem familiarity. When a novel problem is given, individuals can use imagery to transform the situation in a perceptual-like manner so that new information can be identified and rough outlined drafts of potential solutions are designed.

How Imagery Can Be Processed

Kosslyn, Margolis, Barrett, Goldknopf, and Daly (1990) argued in favor of the componential nature of imagery by showing that it is possible to distinguish four distinct types of imagery skills: image generation, maintenance, inspection/scanning, and rotation. Indeed, we can identify more subtle kinds of processing.

Firstly, we *construct* a mental image. This may occur either thanks to a deliberate or a spontaneous process. The *deliberate* construction of a mental image of a possible state of the world can be hinted, for example, by verbal (self)instructions (e.g., “Imagine a cup of chocolate being poured over your knee – a situation you never experienced: What do you feel?”). Mental images can also come up to our mind involuntarily, as it happens during ► [“Dreams”](#) (Barrett 2001) or in mental state such as ► [“Daydreaming”](#), resting (Cai et al. 2018; Feng et al. 2019; Li et al. 2016), or mind-wandering (Chen et al. 2019; Gable et al. 2019; Leszczynski et al. 2017). It has been shown that sleep is a period of incubation that can lead to ► [“Insight”](#) through which we understand the world differently (Lewis et al. 2018; Barner et al. 2017; Leong et al. 2019; Cipolli et al. 2001, 2004; Schoch et al. 2019). In (at least) REM sleep, there is indeed some form of active, albeit involuntary, control of information that brings to light the existence of unusual or unsuspected relationships, so that a form of insight takes place. These conceptual changes also occur thanks to hypnagogic images (Cipolli et al. 2003) and in the so-called

microdreams (Nielsen 2017), short dreams that appear during falling asleep.

A mental image can be *scanned*. We can inspect mental image by “navigating” it or by considering a specific part of it and selecting it or focusing on it. Mental scanning can concern both the *explicit* parts of the image, namely, the parts which we would perceive if we were physically in that situation, or the *implicit* parts. For instance, in the case of visual images, we can identify the parts which are hidden, if we take a particular point of view, because some overlapping occurs or because of occlusion. (If we imagine a cube, we can represent not only the front and upper sides but also the back and bottom sides and the inner parts of the solid.) In this respect, it is worth reporting that children with autism and intellectual disability can represent mentally the occlusion of overlapping objects in the three-dimensional space better than typically developing peer (Treffert 2000) (see ► “Disability”).

A further way to process mental images is to *manipulate* them. As visual mental images, we can rotate or overturn them. As auditory images, we can reverse them (for instance, we can imagine what a melody would sound like if it were played starting at the end and moving toward the beginning). Thanks to these kinds of manipulation, we can represent alternative states of the world and anticipate what would happen if some actions would be applied to objects and situations.

The next process is *transforming*. The manipulations described before preserve the original image. Instead, when we transform a mental image, we change one or more characteristics of it. We can distort an image by expanding or reducing its size (or the speed in the case of auditory images and the intensity in the case of auditory, olfactory, gustative, and somatosensory images), by modifying its appearance (e.g., color), or by deforming the shape. We can also alter a mental image by subtracting or adding parts.

A transformative process, which appeared to be closely linked to the invention of new entities, is the mental visual synthesis, which Finke (1990) proved to be effective to lead individuals to create

original and useful objects. According to this transformation, persons are induced to combine some simple figures mentally and to explore the product of such a combination to realize an emerging meaning, which suggests to invent new products or find new ideas. This synthesis gives the possibility that a global picture resulting from the combination of several partial images has more meaning than its constituent parts. The outcome of the mental synthesis is in fact a new picture that could help to better understand the original meaning. It has been shown that people can be trained to apply this technique more efficiently if they are instructed to follow some strategies. For instance, they can be told that creative products are likely to be reached if figures are mentally manipulated in flexible and dynamic ways by enlarging, miniaturizing, moving, rotating, turning, overlapping them, by intersecting or including figures, and by combining them in unusual ways. It is equally effective the instruction to combine figures to obtain a whole image and then to search for possible different meanings of such an image by trying to interpret it in various manners (Antonietti and Martini 2000).

Individual Differences in Imagery

People differ in the extent to which they can generate, manipulate, and transform mental images, and these differences modulate the efficacy of the use of such images to conceive alternatives to the existing situations.

The feature of mental imagery that was investigated more is vividness (Marks 1973). Studies on the so-called (idiot) savants supported the notion that these individuals excel in constructing and inspecting detailed visual mental images. For example, “calendar calculators” (people who can say with surprising speed on what day of the week a date falls in either the past or future) perform the operations necessary for such calculations through mental visualization as if the subjects possessed an immense numeric “mnemonic tapestry” that they inspect when they compute the

required calculations (Sacks 1985). Furthermore, positive correlations between imagery vividness and divergent thinking skills have been reported in typically developing subjects (Rhodes 1981; Shaw 1985, 1986; Shaw and Demers 1986). The distinction between the ability to generate *object* images and *spatial* images has been more recently proposed (Blazhenkova and Kozhevnikov 2010). Some people are skilled in creating images with a lot of details which they visualize in their mind precisely and vividly. On the other hand, there are subjects who are able to produce schematic mental images where only the essential relationships are represented.

A distinct dimension of imagery skill is control, which concerns the ability to manipulate and transform mental images. Several findings suggest that the manipulation and transformation of mental images lead individuals to discover emerging meanings, which induce to conceive insightful ideas or to create new products (Barolo et al. 1990). However, a study carried out with children addressed the relationships between ► “[Intelligence](#)” and creativity and imagery skills. The performance in tasks requiring to mentally rotate, overturn, and distort visual images resulted to be correlated to intelligence but not to creativity. The opposite was true of the skill in synthesizing mental images. It is likely that the sequential nature of the former tasks needs the contribution of logical thinking, which plays no role in visual synthesis. The latter task, instead, is associated to creative thinking since parallel, holistic processing is beneficial in both (Antonietti and Colombo 2011–2012).

Indeed people differ as regards to their awareness about the roles that imagery plays to support ideation. Positive effects of mental visualization on problem-solving are higher when individuals are instructed to generate mental images after being given the problem, rather than when they receive such a hint before the problem is presented (Antonietti et al. 1994). This suggests that imagery generation is particularly useful when it is orientated toward a specific endpoint, namely, when visual images are created and manipulated by having in mind the goal to be

achieved. Images produced without the constraints and the directions imposed by such a goal can be interpreted and transformed in a wide range of ways, so that individuals are likely to follow unproductive lines of thinking. Thus, it seems that imagery plays a facilitating role in particular kinds of problems (as discussed before) and in peculiar phases of the thinking process. This stresses the need that, in order to employ mental images productively, persons should be able to identify such a kind of tasks and phases. It has been shown that some people consider imagery above all as a mental operation which allows “to see” the problem. They have in mind only a static function of the images. They do not think that they can transform mentally the problem and so they fail to rely on imagery to solve the problem (Antonietti 1999).

Summary

Imagery is a kind of mental representation which can support individuals when they are thinking to possible states of the world, either because they are prompted to find a solution to a problem or to improve the current situation or because they perceive the need to imagine alternative ways to figure out how things are or are managed (see ► “[Imagination](#)”). The intrinsic features of imagery and of the operations, which can be applied to mental images, give reason of why imagery is so relevant to achieve these goals. However, not all individuals can spontaneously generate and process mental images to take benefit from their functional properties.

Eckhoff and Urbach (2008) maintained that imagery is crucial for educators to promote creative thinking in informal and formal learning environments. This supports the attempts to enhance the ability to think to the possible by means of training activities based on imagery. This can be achieved both by devising structured educational programs aimed at improving imagery skills and at addressing such skills to the accomplishment of creative task and by inducing people to develop the spontaneous tendency to rely on mental

images when creativity is needed in everyday-life situations.

Imagination

Tania Zittoun¹, Hana Hawlina¹ and Alex T. Gillespie²

¹Institute of Psychology and Education, University of Neuchâtel, Neuchâtel, Switzerland

Abstract

Imagination can be defined as the process by which we temporarily leave the here-and-now of current experiences, to explore and play with the past, the future, and alternative spheres of experience. In recent work, we have proposed a sociocultural approach to imagination, conceptualized as a “loop,” by which the mind or the flow of consciousness temporarily disengages from immediate situational demands (Zittoun, T., & Gillespie, A. (2016). *Imagination in human and cultural development*. London: Routledge). In this entry, we argue that the dynamics of imagination can lead to changes in the boundary between the possible and the impossible, and beyond. More specifically, we propose a three-layer model and show how, through a double-propelled motor (the self-other dynamic and the semiotic-material dynamic), imagination

enables us to explore – individually or collectively – the boundaries across the not-yet-imagined, the impossible, the possible, and the actual.

Imagination and the Possible

From Classical to Sociocultural Understanding of Imagination

Imagination can be defined as the process by which we temporarily leave the here-and-now of current experience, to explore and play with the past, the future, and alternative spheres of experience. In recent work, we have conceptualized such process as a “loop,” by which the mind or the flow of consciousness temporarily disengages from immediate situational demands (Zittoun and Gillespie 2016). Imagination breaks free from the logic of the material world; the possible and impossible are no longer subordinated to the actual, but expand and transform it.

Although imagination is an individual experience, we propose that it is also profoundly social and cultural. These simultaneously personal and cultural aspects are common to all semiotic activity (Valsiner 2007). For example, we use words to not only express but also constitute personal experiences, but the words come from our culture. Indeed, going further, the words (and in this sense our culture) enable new experiences through language (Vygotsky 1986) – such as a novel creating personal insight. And so it is with imagination: it arises at the intersection of immediate experience, personal history, culturally shared meaning complexes, and symbolic or cultural resources (such as books, films, narratives) (Zittoun and Gillespie 2016). What was imagined by our ancestors thousands of years ago, what is imagined today, and what might be imagined in the future are different because what is imaginable is part of culture, growing along with it, and, enabled by long-standing (i.e., narratives) and

new (i.e., virtual reality) technologies (Gillespie et al. 2018).

This sociocultural conceptualization of imagination departs from classical views in philosophy, psychology, and the social sciences, whereby imagination is a faculty, either opposed to cognition (Descartes 1641/1996), or a representational universe (Schwartz and Ryan 2003). A sociocultural approach resists the idea that imagination is essentially reproductive (Descartes 1996): although it assumes that imagination has to draw on existing material (Bartlett 1928; James 1890), it conceptualizes it as producing novelty. Finally, against approaches that consider imagination as the faculty to produce “images” of the mind (Descartes 1996), the current approach considers that imagination can occur through a variety of semiotic modes and be linked to a variety of sensory modalities, including embodied ones (Gfeller 2017; Hargreaves et al. 2012).

A sociocultural conceptualization of imagination begins with lived experience. It is triggered by current experiences, past experiences, or aspirations for the future. And once the loop is initiated, and experience breaks the bonds of the here-and-now, then three dimension of imagination become visible (Zittoun and Gillespie 2016). The first dimension is temporal: imagination can be oriented toward the past, and so remembering can be seen as imagination about the past; toward the future; and toward alternative presents. The second dimension is that of generalization: imagination can be about concrete and specific experiences, such as the taste of coffee, but can address general or abstract entities, such as the good in the world. Finally, the third dimension describes how plausible the current imagining can be considered in a given social setting: imagining becoming vegetarian in very plausible in twenty-first century Europe, but much less so in the stone age; imagining life on Mars has become much more plausible over the last century, although it has not yet been realized. This latter dimension is similar to the possible, but more socially defined (i.e., plausibility depends upon a community to make something not only possible but plausible).

But imagination is not just about our experience leaving the here-and-now and forever growing in either abstraction or implausibility. The loop of imagination brings us back to the present here-and-now. Through this return, imagination contributes to the world, creating personal experience and sometimes transforming our collective culture (e.g., it leads to a new discovery, an innovative idea or a new fantasy movie). In everyday life, one may be imagining because one needs a new bookshelf or because one is bored; one can draw on personal memories, go on the Internet, read an encyclopedia or the Bible, engage with arts or discuss with friends to feed one's imagination; and in closing the loop imagination can lead to a laugh, a bookshelf, or a political revolution.

If imagination is not merely a departure from reality but a contribution to the social construction of individual and collective future realities, then imagination plays a core role in human and cultural development. On the one hand, in early childhood, imagination is present in play and the creation on one's own zone of proximal development; in adolescence and adulthood, imagination is fundamental in the exploration of choices, definition of projects, but also daydreaming and remembering; in old age, imagination allows to reread one's lives or the course of history one has met, and still to be oriented toward the future and what is to come (Harris 2000; Hviid and Villadsen 2018; Singer and Singer 1992; Zittoun 2017; Zittoun and Saint-Laurent 2015; Zittoun and Sato 2018). On the other hand, culture and societies develop through the imagination of a few that may become shared or collective imagining, which support communities (Daiute 2018), and which may bring people to the Moon or to a revolution (Jovchelovitch and Hawlina 2018; Zittoun and Gillespie 2018).

In summary, imagination is a multimodal, embodied, semiotically mediated, and deeply cultural and individual experience that can contribute not only to the development of the individual but also to the development of society (Zittoun and Gillespie 2016). Imagination is crucial for understanding humans as creative in constructing their own futures – futures that are not only limited to what is possible (e.g., a new invention) but can

also include the impossible (e.g., new fantasy landscape for a series of movies). Moreover, as we will show in the next section, tensions within and beyond imagination can lead to changes in the boundary between what is possible, and what is impossible. In other words, imagination is the core process by which we explore, individually or collectively, not only the possible (e.g., the past as it was or as it could have been, the present that we do not experience, or what is about to happen or will never do) but also the impossible (e.g., flying bicycles or a world without national borders), which is the germination of future possibility.

Imagination at the Boundaries of the Possible, the Impossible, and Beyond

Imagination, we will argue, is the process by which we can work, individually and collectively, at the boundaries between the not-yet-imagined, the impossible, the possible, and the actual. We represent these domains as nested sets, in Fig. 1. At the center is the actual, which includes that which has been socially actualized (possibility realized), then there is possibility itself, surrounded by impossibility, which in turn is surrounded by the infinity of the not-yet-imagined. In what follows, we will explore these domains in turn, and describe two processes that drive the re-shaping of these boundaries.

In sociocultural psychology, the possible has been conceptualized as a relational phenomenon arising out of tensions between self–other, person–world, and past–future (Glăveanu and Gillespie 2014). It is the human capacity to go beyond the real or the actual (i.e., what is), to engage in an exploration of what is not and what could be, and potentially expand the actual (Dewey 1910; Glăveanu 2018). In that sense, the actual and the possible are not opposites, but deeply interconnected since “our sense of possibility and its exploration are grounded in what is already actualised and, most of all, transform our experience of the actual” (Glăveanu 2018, p. 519). And once a possibility has been actualized and became a shared cultural element, it can act as a novel resource used to imagine further possibilities. Hence engaging with the limits of the

Imagination,**Fig. 1** Imagination and the possible

possible enables us to escape the material constraints of a situation and re-envision the situation in terms of what we can make it become (Unger 2007). Thus, imagination acts precisely as the process that sustains, nourishes, and transforms the possible. Imagination operates in recursive looping between the actual and the possible, resulting in a dynamic co-construction where the actual shapes the possible and provides resources for imagining alternatives, while the possible can steer action (individual or collective) to reshape the actual.

Imagination, in our conceptualization, subsumes not only what is actual or possible but also what is impossible; it is a larger process through which these elements are reconfigured. Magical kingdoms with unicorns and dragons, planets where people can change sex on a whim, or alternative worlds if another party had won the elections have no possibility of actualization, yet they motivate possibility (i.e., inspiring the writing of a novel or the formation of a new political movement). Because it is often characterized by the impossible in contrast to the possible, the imagination was often regarded as infantile, escapist, unproductive, primitive, and even associated with mental disorders (Haiven and Khasnabish 2010). Nevertheless, reversing or completely suspending reality from time to time can foster a playful and open-ended engagement with the world, loosening the fixation of how things are and questioning the existing state of affairs. If the domain of the possible is ever to

expand into the domain of the impossible, it requires a reconfiguring of this boundary through the imagination. Most social movements and political revolutions began with an impossible idea, and then, as the imagination became shared, the plausibility increased, the impossible became possible and, sometimes, even actual (e.g., the welfare state). Such transformations of the boundary between the possible and the impossible can radically transform the existing state of affairs (Day 2016; Khasnabish and Haiven 2014; Pérez Huenteo 2019).

From this point of view, even the far fringes of impossibility are important. Beyond the impossible (i.e., what a person, or humans as a group, have conceived as impossible) is the domain of the not-yet-imaginable (i.e., that which has not even been imagined as either possible or impossible). In effect, the scope of imagination of individuals and societies is bounded by a so-called imaginative horizon (Crapanzano 2004; Zittoun and Gillespie 2016), the limit of our symbolic universes that can only be defined retrospectively, once it has been pushed outward/extended (Bruner 1990) or from an outside perspective (Crapanzano 2004). Hence, the domain of the not-yet-imagined that can only be seen with hindsight includes, for instance, the smartphone or gene manipulation during the Palaeolithic Age. What is not-yet-imagined today is logically impossible to conceptualize or write about. While our society often celebrates people and groups who manage to turn the impossible into

the possible (i.e., the Moon landing, heart transplants), the imaginative achievement of discovering a new impossibility should not be underestimated; for these are the germinations of tomorrows possibilities.

The not-yet-imagined is thus an opaque space of potential that can be accessed by the imagination only through the emergence of novel ideas and artifacts. The imaginative horizon is often set by the social and technological development of the society, for example in the Middle Ages, the idea of live televised news would have been unimaginable, whereas in 1900 when photography and telephones were already familiar technologies, John Elfreth Watkins (1900) was able to foresee it happening in the next 100 years. On the other hand, flying has long been within human's imaginative horizon. The sight of birds flying has motivated inventors for millennia, but the majority of people imagined it to be impossible.

The boundaries between the not-yet-imagined, the impossible, the possible, and the actual are crossed and repositioned through to the dynamics of imagination. This is the case individually, when for instance a child starts imagining becoming a parent, which had previously been not-yet-imagined; but, this can still be impossible (e.g., the child is too young) and then a possibility (e.g., they become old enough), which then may be actualized or not. The boundaries are also crossed in the case of social change and history, in which case the collective imagination is at work. In such cases, imagination of, or at the boundary is often the site of social contestation. This can be in the direction from the impossible to the actual, such as in the case of the civil rights or woman suffrage movements, or in the opposite direction of curtailing human rights and closing down semantic and physical borders, which narrow the scope of the possible. At these boundaries two dynamics are visible.

First, boundary changes can be generated by differences of perspective about whether something is possible or impossible, which we will call a *self-other* dynamic. Two partners may imagine refurbishing a house, but their divergent perspectives may bring discussion about what is impossible to consider, what could be done, and

which design will be actualized. Minorities debate with majorities about what is or is not possible, proposing, resisting, and creating alternatives that can be threatening (Gillespie 2008). Recruiting a majority can make something impossible in the sense of not being socially feasible (i.e., taboos, unquestioned assumptions), or it can mobilize the resources necessary to make something not only possible but actual (i.e., a Moon landing). Normative imaginative horizons in the eighteenth century, when slavery was widespread in the USA, made it unimaginable for most people that a person of color could become the country's president, which only became possible after centuries of contestation and actualized in 2008.

Second, boundary changes can be initiated by tensions between the semiotic domain and the material or concrete domain, a *semiotic-material* dynamic. At an individual level, after the end of communism in the Czech Republic when deep fryers were imported from the west, young Pavel discovered the (embodied) taste of fries that enabled him to imagine the possibility of opening a food-truck (Zittoun 2017). Conversely, imagining certain tennis moves may actually facilitate their realization (Markman et al. 2009). Such dynamics also take place collectively: not only can the real puncture the symbolic domain (i.e., the Chernobyl reactor failure demanded acknowledgment that such a failure was possible), but the symbolic domain can shape the real (i.e., belief that heavier than air crafts could fly led to their actualization).

Propelled by these two dynamic tensions (self-other and semiotic-material) imagination becomes the main process that enables people and societies to move an idea across boundaries and to expand or contract the boundaries themselves. There are many accounts of science fiction inspiring scientific research that led to the realization of initially not-yet-imagined or impossible ideas, such as space travel, virtual reality devices, and self-driving cars (Alkon 2013; Johnson 2011; Zittoun and Gillespie 2016). In such cases there are actually two landmark moments: first, when an impossible idea is first imagined (i.e., Lucian in *A True History* in 125–180 a.c. imagining visiting the Moon (Lucian 2014)), and second, when it

transforms from a possibility into actuality (i.e., landing on the Moon). From initially imagined impossibility to actualization, individual and collective imagination have been at work. The movement of imagination was supported by a constant self-other dynamic, for instance through the ideological battle between the USSR and the USA cloaked as a technological race. Also, it was energized by the dynamic taking place between the semiotic and the actual: Meliès (1902) needed to have seen the first canon to imagine shooting astronauts to the moon using a huge canon (Zittoun and Gillespie 2018). Today, half a century after the Moon landing, its realization is still doubted by a small, but vocal minority who insist that reaching the Moon remains impossible – this is an extreme example of how different communities can maintain different perspectives on what is impossible, possible, and actual. What is often at stake is not so much what is ultimately possible or impossible, but rather the extent to which we are collectively choosing to dedicate resources (money, legislation, education) toward creating possibility. Possibility is not, in this sense, an inherent property of the world; rather, it is a social achievement.

In many cases, we can see a progression from the not-yet-imagined to the impossible, becoming possible, and finally actualized. However, the process is rarely so linear and unidirectional; there are often counter-movements and resistance. We can also observe the reverse processes, where things that were once possible become impossible or even unimaginable (e.g., collective forgetting, loss of resources and cultural artifacts, censorship).

In the USA in 1960s and 1970s, second wave feminists fought for bodily autonomy and reproductive rights, which caused a seismic cultural shift and led to the legalization of abortion in 1973 (Kline 2010). However, in the first months of 2019, over 20 US states introduced some form of an abortion ban in their legislature (“What’s going on with US abortion rights?” 2019). If before, notions and rights that were initially seen as impossible for women became progressively

actualized, today we are witnessing a reversal where choices are taken away and what used to be possible is becoming less possible. This shift is driven by the differences in perspectives on gender equality, reproduction, religious beliefs, and autonomy vs. control over women’s bodies, contested in courts and public debates as opposing parties re-negotiate and constrain the normative boundaries. Such narrowing down of the possible is not evident only on the societal level, but it also reconfigures what is possible and impossible in the life trajectories of individual women and their families, as they have to re-imagine their lives through the prescribed channels of compelled motherhood, while previous possibilities may become impossible (e.g., going to college or different career trajectories).

Conclusion: We Are Responsible for Actualizing Our Own Future

Our review of the relation between imagination and possibility has taken us to the heart of how humans build their own futures. Of course, humans are constrained not only by the laws of physics but also their own norms and expectations (Valsiner and Brinkmann 2016). They can expand these through imagination, yet as past experiences, existing cultural artifacts, narratives, and social representations act as the necessary resources for imagining, these can also channel the imagination along predictable pathways and constrain what is possible to imagine. But, equally, the history of human culture teaches us that the not-yet-imagined likely has many surprises in store for us and what is impossible for one generation can become possible for the next. While such an expansion of human capability can seem progressive and enabling (Dewey 1916), it needs to be tempered by recognizing our own responsibility in the process (Unger 2007). Human imaginations, and decisions to bring some impossibilities to the realm of the possible, or the other way around, will shape the impact of climate change, the extent of inequalities, and the

course of the digital revolution. The paths we choose will create not only our future but our resources for imagining subsequent futures. Once something that was initially unimaginable becomes possible or actualized, it becomes itself a potential resource for subsequent imaginings, opening up new spaces of possibilities, impossibilities, and questions that catalyze and canalize future imaginative horizons.

Impermanence

Kiene Brillenburg Wurth
Comparative Literature, Utrecht University,
Utrecht, The Netherlands

Abstract

Impermanence is a central concept in Buddhist philosophies. These philosophies – in their immense diversity, as part of different schools or currents – generally hold that suffering is needlessly created through an attachment to things that had seemed permanent, or that one had *craved to be* permanent. However, in the world according to Buddhism, life is movement or change: everything is in process, and bound for decay. If one thinks one is held together by a substantial, continuous I in this life, one is mistaken. No-self exists. What one thinks of as an I, is an ever-changing configuration of aggregates or skandhas: bundles of matter, sensation, perception, mental formation, and consciousness. Buddhist philosophies thus challenge thinking, feeling humans to let go of the self, and to re-consider themselves as coming out of this world: as entangled with the earth. How can such a relational “thinking otherwise” about human no-selves change academic ideas on creativity? How can creativity, and creative expression, in other words, be rethought *beyond a self*?

(Five) Aggregates/Skandhas · Attachment (*upādāna*)/non-attachment (*nekhamma*/Chinese (in Zen Buddhism) *wú niàn* (無念) or no-thought) · Cartesianism · Creativity · Creativity beyond a self · Decoloniality · Distributed Creativity · Ecocriticism/ Ecofeminism · Genius · Historiometric research into creativity · Humanities ·

Parts of this entry have been published in my “Creativity from a Comparative Perspective: Processual and Buddhist Views.” In Chiara Robbiano & Sarah Flavel (Eds.). *Key Concepts in World Philosophies*. Bloomsbury, 2022.

Impermanence (*aniccā*) · Processual view of the self · No-self (impermanent self) (*anattā*) · Relationality/entanglement · Suffering (*dukkha*) · David Hume · Immanuel Kant · Thich Naht Hanh · Val Plumwood · Arthur Schopenhauer · Walpola Rahula Thero · Alan Watts

It is still believed that Buddhist philosophies (including a range of different schools or currents) pivot around the idea that life is permanent suffering (*dukkha*), and that the only way to be released from such suffering is detachment. Nineteenth-century European philosophers like Arthur Schopenhauer, duly influenced by Buddhism, have helped to foster this belief: at the root of suffering is craving, and craving is endless (Schopenhauer). When craving is satisfied, its cycle starts anew – and so does suffering – and when craving is not satisfied, suffering continues with it. A way out of this hopeless loop, Schopenhauer believed, is aesthetic contemplation. Such contemplation amounts to brief moments in which one feels detached from the world of craving as a *pure subject of knowing*, cognizant only of Ideas, not of things to be had (Schopenhauer, Brillenburg Wurth). Yet, these moments are moments only: intermittent, gone before you know it, to be eclipsed by craving again – though insight may transform suffering in time. Schopenhauer’s philosophy is pessimistic, as he did not believe in progress like Hegel did, but such pessimism is in no way key to Buddhism. In fact, whenever one sees an image of the Buddha, one encounters a smiling, content, and peaceful countenance. That peacefulness, it will be seen in this section, comes with the insight that one merely needs to let go of certain erroneous assumptions – of ignorance – to let go of suffering. This insight boils down to the fact that suffering is needlessly created through an attachment to things that had seemed permanent, or that one had *craved to be* permanent. However, in Buddhist philosophies, life is movement, change; everything in life is impermanent, even our very selves. Indeed, as Walpola Rahula stressed, *dukkha* itself, familiarly meaning suffering, misery, and the like, also has a deeper meaning of

insubstantiality and impermanence (*aniccā*) (17). Finding happiness in life is coming to terms with impermanence, including that of the self, in so far as a self is conceived as the illusion of a unified whole of one’s conscious life: an extensive I.

In this entry, I explore this idea of an impermanent self in Buddhist philosophies, while also assessing the implications of such impermanence to European and Anglo-American research in creativity. What are the possibilities for such research when we disengage creative thinking from ideas of a continuous I? What, in other words, is the potential of Buddhist philosophies to possibility and creativity studies: what will creativity entail beyond encrusted conceptions of a permanent, stable or “owned” self? If suffering in Buddhist philosophies (ranging from Theravada and Mahayana to Neo-Buddhism) arises out of an ignorant attachment to illusions of permanence, a release from such attachment may also release scholars from ill-conceived ideas of autonomy, genius, achievement, and innovation that all come, in one way or another, with the idea of a separate self. How can the idea of such an “owned” self be de-composed? The question is relevant, as ideas of “the” self, as well as most of the cultural terms of individuation (as regards gender, class, and race) in the global North, have been deconstructed as random, suppressing, and violent (Kitchner). Decomposing the self as an agent of creativity, I argue, thus also opens up decolonial pathways in creativity and possibility studies: a thinking otherwise (Mignolo/Walsh).

In a popular talk entitled “Myth of Myself” (1972, from the *Tao Philosophy Series*), the controversial philosopher and public speaker Alan Watts expressed his amazement at how humans in “Western” cultures speak about themselves. “Most of us,” he said, “feel ‘I’ – ego, myself, my source of consciousness – to be a center of awareness and of a source of action that resides in the middle of a bag of skin.” One typically thinks of this I as a substance located somewhere “behind the eyes and between the ears,” rather than being an integral part of the body-as-process (Watts [1972] 2019: 1.1.7, no page). Hence, Watts continued,

We are not accustomed to say, “I am a body.” We rather say, “I have a body.” We do not say, “I beat my heart” in the same way as we say, “I walk,

I think, I talk.” We feel that our heart beats itself, and that has nothing very much to do with “I.” In other words, we do not regard “I, myself” as identical with our whole physical organism. (Watts 1.1.7)

Not saying “I beat my heart” or “I am my body” indicates what – ecofeminist philosophers like Val Plumwood have called – a hyper-separation of mind and body: following the Cartesian dictum “I think, therefore I am,” dominant and normative modes of thinking in the global North have conceived of the human as being the rational (and male) other of nature (Plumwood). By contrast, following East Asian currents of thinking, Watts starts from a *relational* model of mind and body, humans and other beings, or “nature”. Though many people think and speak as if they “came into this world,” Watts argues, the opposite is in fact the case: they “come out of it.” “What,” Watts continues, “do you think you are? Supposing this world is a tree. Are you leaves on its branches or are you a bunch of birds that settled on a dead old tree from somewhere else?” The earth, he concludes, “peoples,” just as an apple tree “apples;” people are expressions or “symptoms” of the earth (Watts 2019: 1.1.7). To that extent, people are *entangled* with the earth: they *partake* of earth elements. The idea of such entanglement is central to current ecological critiques, but it has circulated in Buddhist and Taoist philosophies for thousands of years already (Ghosh, Clark).

The illusion of a gap between mind and body, reason and sensation, humans and earth, and humans and other earthlings has triggered a hostile stance toward nature. Since the Enlightenment, philosophers in the global North like Immanuel Kant have claimed that it is the destiny of humans to transcend nature, and dominate it by means of the supersensible faculty of reason (Kant). (Though critics like Theodor Adorno, deeply suspicious of the Enlightenment project, argued against the idea of a mind transcending nature. Human subjects, he stated in *Aesthetic Theory*, are not positioned in isolation. In the experience of the sublime, for instance, one senses one’s entanglement with, instead of an apartness from, nature). In the same vein, Watts claimed,

scientists, entrepreneurs, and politicians think they should “conquer” space (1.1.7). It is not surprising that the race for space between the USSR and the USA in the 1950s was one of the prime incentives for creativity research in the global North, and laid the ground for current understandings of the term. This historical base illustrates how deeply misconceived that term is as an ability to find ever-new and useful solutions to challenges that the world poses to human beings. Instead of considering themselves growing out of that world, humans are in perpetual conflict with it. What if one turned the tables and considered human beings as natural *process/es*?

For such a processual view of the self, I turn to the *Abhidharma* (ca 400 BCE–200 CE, literally meaning: *concerning the teachings* or (in another interpretation) *higher teachings*); the ancient Buddhist texts that offer a theoretical account of perception and experience. Many scholars see these texts as the systematic counterpart to Buddhist practices of meditation, evolved as they did out of a core (*mātikās*) of doctrinal concepts listed in charts or diagrams (Jacobs 2017: 1–19). Beth Jacobs accordingly calls this core a “periodic table of experience” (Jacobs 2017: 5). As Monima Cadha explains, the *Abhidharma* teachings offer an account of perception and experience that is different from dominant European and Anglophone meditations on the self and consciousness (Cadha 2016). More precisely, Cadha posits, “the *Abhidharma*-Buddhist writings are replete with attempts to explain the phenomenology of experience in a no-self world,” while non-Buddhist philosophies – and psychologies – precisely start from a self-world (Cadha 223–224). That is to say, the idea of a self that exists as a nexus of consciousness and an anchor to hold on to in a world full of doubt in non-Buddhist, Cartesian thought, is deconstructed as a delusion and a source of suffering in Buddhist thought. No-self means impermanence, self means delusional control.

As there are many different views on (the interpretation of) no-self (*anattā*) among Buddhist philosophers, the idea (or the misapprehension) of what a self might be, is just as open to discussion (Cadha 225, Jacobs, Davis, Rahula). I here maintain that self is not a “quality” or “content”

but rather the “how of experience,” without there being even a minimal self to be presupposed (Cadha 225). Now, if the Abhidharma explains the how or presence of experience in a no-self world, then what does consciousness of experience entail? This cannot be consciousness of a thinking “I”. It is neither *necessary* nor *logical* to presuppose such an I, conceived of as an entity that is continuous over time. First, whatever I perceive in the world, or in thinking, I cannot catch myself in that perception. Second, Abhidharma Buddhist philosophies show one does not need to postulate an “I” as an agent of experience because “causal connections between mental states” make such an ‘I’ superfluous: these states will arise and then disappear anyway (Cadha 238). No need, and no use, to cling to a self that is owning these states as it persists over time (Jacobs 70). Such a self cannot logically exist because no entity can exist permanently in Abhidharma Buddhist philosophies: things originate and are sustained interdependently. Here, everything materializes only impermanently, the mind included. Experience in Buddhist philosophies, then, is not *owned by an agent* because such ownership implies continuity and control. One has no control over the sensations and mental states that arise in consciousness, let alone over consciousness itself. These sensations and states simply come and go (Naht Hanh).

What many European and Anglophone philosophers, psychologists, and cultural critics have therefore taken for an agency that needs healthy reinforcement – the self – is regarded in the Abhidharma as unhealthy identification with the delusion of an internal entity bounded and “separate from the rest of the world” (Cadha 239). For in a Buddhist universe, nothing can be self-same and apart. Everything originates interdependently, in relation to each other, out of each other, and in contrast to each other (Jacobs 18, Rahula 20). Everything – including the self – is part of a web of causations that bring forth temporary constellations. A constellation arises, and then it disappears again: reality is a flow of multiple, momentary, and mutually conditioned events. The self is no less part of that flow than anything else: it is an event that occurs differently, in

different settings, time and again. In the Abhidharma, the self is therefore analyzed as a configuration of *five aggregates* or skandhas: matter, sensations, perceptions, mental formations, and consciousness (Jacobs, Rahula). What is called a self in patriarchal, occidental thinking, is a mere temporary *effect* of particular configurations of the five aggregates in the Abhidharma texts: a mind-body complex that changes with every nano-second in the stream of life. Thus, the first of these aggregates concerns matter or the physical body (*rūpa*). It consists of the four elements (just as the earth consists of these elements) solidity, fluidity, heat, and motion, as well as of the five senses and their objects. The second concerns sensations (*vedanā*), again including the five senses *plus* the sense of the mind (*manas*), which is likewise seen as an organ, albeit one mediating concepts or ideas (Rahula 20–21). The third aggregate concerns perceptions (*sañña*) or the recognition of sensations, just as the fourth includes thoughts, or mental formations/intentions (*sankhāra*), while the fifth refers to consciousness (*viññāṇa*), differing from “Western” conceptions of consciousness to the extent that it is – unlike the first four skandhas – without an object or substrate. Rather, it is awareness-awareness. As these aggregates occur in tandem, so does a self become manifest momentarily. But since these skandhas do not last, that self does not extend beyond their immediate occurring either. Put differently, no self behind the occurrence of the skandhas can be presumed.

Like the process philosopher Alfred North Whitehead, the eighteenth-century philosopher David Hume may have come close to this Buddhist conception of the self as aggregates of matter, sensations, perceptions, thoughts, and awareness-awareness. He pointed out that the self is something we postulate on the basis of the experiences that we have, but this postulation is a fiction: “I may venture to affirm of the rest of mankind, that they are nothing but a bundle or collection of different perceptions, which succeed each other with an inconceivable rapidity, and are in a perpetual flux and movement” (Hume 162, Giles). Beyond these perceptions, there is a vacancy, not an I organizing existence.

Consequently, there is nothing permanent inside us to mark us apart from nature, which is, after all, marked by infinite change. As thus essentially *impermanent*, the five aggregates are likewise *dukkha*, in its third sense of conditioned states, in so far as they lead one to attach to the delusion of a self that is owned, separate, permanent, or continuous (Rahula 19–20).

So far, I have shown how no-self (*anattā*) in Buddhist philosophies is not separate but continuous with nature, that, as such, it is just as impermanent as any other natural process, and that – therefore – there is no ground to postulate an enduring self that is somehow transcendent. To postulate such a self, and to attach to such a self, is one of the prime causes of suffering in human lives. All one has to do is to not-attach for the suffering to end. As emphasized in Zen Buddhism, It will not take a heaven-like *nirvana* to accomplish this feat: *nirvana* can be realized in every moment one can let go of self-attachment. Ironically, as cultures of individuality, “Western” cultures have organized themselves fundamentally around this delusion of an enduring self. It would lead me too far here to enter into the multiple ways in which this organizing has taken place, but one of them, art and creative practice, will suffice to illustrate my point. Research into creative practice and thinking has been predominantly focused on individuals, from historiometric research seeking to understand the productivity of “eminent” (mostly white male) thinkers, musicians, composers, writers, or artists, to traditional research in the humanities on the works of those so-called eminent individuals, their ideas, the spread of their ideas, and copyrights attached to them (Simonton). Theories of distributed creativity (Glaveanu) have countered such self-focused inlets to creative thinking and practice, yet so far, they have not pursued or thought through the consequences of *no-self* to creativity.

Can a creativity beyond the self, a creative practice of no-self be even imagined from within a “Western” framework? Yes, when one thinks of artistic currents such as conceptual art that denounced authority/authorship – developed in

the mid-twentieth century when Tibetan Buddhist and Zen Buddhist ideas started to influence “Western” composers, artists, and poets – or collective creative practices such as quilting that denounce originality and individual genius. At the same time, creativity beyond the self remains a challenge within a “Western” framework: conceptions of art, but also art education, and the production and distribution of art and literature have been defined and organized in such a way as to privilege the idea of a continuous self that evolves over time – a subjectivity expressing itself to others, growing in time, changing, yes, but always as part of a single, overarching personality. Answering to this challenge would involve an idea of creativity beyond *novelty* and *usefulness*: beyond achievement, or perfectible skill (Brillenburger Wurth). It would involve an idea of creativity beyond the human self as agency, and require a theoretical frame that is, by definition, ecocritical: that sees the production of humans (in whatever field, art, or otherwise) as arising out of their entanglement or continuity with nature. If the traditional, individualistic take on creativity is about bringing the new and useful into being, creativity beyond the self is about presence or deep attentiveness to what comes along. It is about freedom, as much as art can be when it releases one from habitual patterns of thought, experience, and perception. For that matter, no distinction between human-made ideas or products, or artifacts found in nature, such as the blossom of a tree, is needed or desired to think about creativity without a self. What matters, perhaps, is the trace of impermanence that such products and artifacts likewise display: a reminder to not-do attachment, to accept change, and live with it.

Inclusion

Sylvia De Chiaro and Tícia Cassiany Ferro Cavalcante

Federal University of Pernambuco, Recife, Brazil

Abstract

Starting from a dialectical stance in which statements always exist in the condition of an opposite, this text proposes thinking about inclusion considering that it is only understandable in relation to its opposite, exclusion. What makes an individual be excluded in a society can be approached from different points of view. Here, the objective is to reflect about the place of the word as a driver of the individual within the exclusion–inclusion spectrum. As in a dance, individuals move from side to side as the “space of the word” is less allowed or given more opportunity. It is in it, in the word, that a human being realizes and asserts him/herself as a being of identity and author of his/her own history and as a social being, worthy of space and finally of inclusion. It is the word that transports a person from one end of the spectrum to the other. However, we are not talking about any random use of the word here, rather one that allows this movement. The word that does not need sound, but that exudes positioning in the world, that opens space for the constitution of a unique identity in the middle of negotiations of meanings, in an ongoing debate among voices in a universal symposium. The possibility of inclusion is proposed here, therefore, in light of a specific type of language that supports this reflection: that of argumentation. Among the possible cuts of this inclusion–argumentation dyad, in this text the focus of the inclusion axis is people with disabilities.

Keywords

Inclusion · Argumentation · Language · Negotiation of meanings · People with disabilities

This text raises a discussion about the possibility of inclusion through argumentation. The fundamental idea that will permeate the whole construct presented here is that participation in situations of argumentation constitutes a privileged path to enable individuals, who are often socially excluded, to advance towards inclusion. In this exclusion–inclusion spectrum, this peculiar discursive practice that compels individuals to assume and negotiate a position in the world allows them to be seen as people with an identity, most of the time unrecognized. The “space of the word” brought forth by argumentation is seen here, therefore, as a space for the exercise of citizenship and as an important support for inclusion.

Within the perspective presented here, it is possible to approach the inclusion – as broadly as possible – of all people who for various reasons have been placed on the margins of society due to their peculiarity, which at some point deviates from the socially established pattern, silencing them and thus making them invisible. In this text, the framework given to inclusion is that of people with disabilities. That is, the central concern will be to point to argumentation as a possible intentional discursive strategy for the inclusion of these citizens. It is now necessary to bring a historical reflection on how people with disabilities have been segregated and discriminated against and demonstrate how they have played (and still play) precarious modes of social participation (Meletti 2013). Until recently, people with disabilities experienced a long history of invisibility and segregation (Kassar 2013; Mazzota 2005; Guebert 2007; Junkes 2006).

Historical Review

The process of social exclusion that still prevails today is historic. In Europe, in the eighteenth and nineteenth centuries, theories of heredity of intellectual disability and human degeneration contributed to an intense process of institutionalization of people with disabilities. In this scenario, the concern in identifying the “normal” and “abnormal” in medical-pedagogical science grew in several

countries, hierarchizing humanity and denoting the presence since days of old of the dialectical logic (see chapter ► “[Dialectics](#)”) of thinking about reality from its contradictions, including all the tension that determine them.

The processes of medicalization and pathologization of people were configured within a proposal of indiscriminate institutionalization, by categories of disability, which began to occur in the nineteenth century. In 1905, the contribution of the intelligence scale, according to mental age, contributed significantly to this process (Kassar 2013). The work of Binet and Simon in the French government emerged, enabling the measurement of the intelligence of all children in order to separate the “normal” students from the “abnormal” ones, with the justification that it would benefit the schooling process. It is not difficult to imagine that in these different and hierarchical environments, conceived within this range of opposites, the “space of the word” turns cloudy until it reaches invisibility in the environments destined for the “abnormal.”

For a long time, we lived in a society in which the ideological standard of normality prevailed. In this sense, the person with a disability had a condition that kept them away from the modes and functions seen as “normal.” This duality between “normality” and “abnormality,” marked among other aspects by the different usage possibilities of the word, is largely responsible for the processes of discrimination, segregation, and exclusion of people with disabilities that still prevail in our society. For them, the word, as a representation of what is possible toward a personal and social position, reflects a change in the long history of human disqualification. For Meletti (2013), because the strange and the unknown constitute a threat, they ended up being configured in interactions laden with prejudices and stereotypes that established attitudinal barriers. In this context, disability, in the sense of pathologization, was seen as the only attribute of the human being, constituting a social burden of disadvantage and discredit and yielding to those inserted in the category “disability,” the silencing of their voices. Thus, there was a homogenizing perspective in which a person was not allowed to be seen as a

whole, nor in his/her own personal and social identity. The capitalist mode of production is a great ally of social exclusion, and in our society there is an exclusion–inclusion duality, as if they were constitutive parts of the same process, submerged in a social plot that sustains its interdependence (Kassar and Rebelo 2018). We live in a society with inhumane modes of social participation, which places some people at a secondary level, while valorizing an idealized standardization. In the 1970s, based on the cost–benefit ratio, the theory of human capital started to be used in special education, bringing about a new direction of educational policies in several countries, with the prerogative that people, when treated, can become useful and contribute to society. The idea was “to teach people with disabilities to live as normal a life as possible.”

In order for there to be a change in this exclusion/institutionalization paradigm, responsible for reducing the possibility of participation and therefore, of inclusion, some important movements took place worldwide, such as the Education for All conference, in Jomtien, Thailand, in 1990, which defended, in its Article 3, a look at the basic learning needs of people with disability. Another important movement was the Declaration of Salamanca, in 1994, which focused on the dissemination of the concept of inclusive education, a landmark for the inclusion of people with disabilities. The most recent international document is the UN Convention on the Rights of Persons with Disabilities, adopted in 2006, with numerous countries as signatories, addressing important aspects for the social inclusion of people with disabilities.

This inclusive scenario tries to accommodate the different ways of learning and breaks with the logic of normalization and the production of capacitism (Bock et al. 2018). School inclusion is a movement that aims to guarantee everyone’s right “to be a person,” as a possibility that has been historically denied, without demanding homogenizing modes of doing and signifying. Nevertheless, there is no consensus on the practices for schooling these people.

In this scenario, some proposals emerge, such as the field of Disability Studies in Education,

which has focused on educational spaces that are more welcoming to human functional variation. There are also proposals that think about inclusion configured in the idea of schooling for all, considering the different ways of learning, with an appropriate curriculum for the various skills of students, taking into account that people with the same disability have different needs in their schooling (Bock et al. 2018). In this line of thinking, a recent approach is the Universal Design for Learning (UDL), which eliminates methodological barriers in the learning contexts and expands choice possibilities. This proposal breaks with the idea of having one plan for the whole class and another plan for students with disabilities, so that people with different challenges can have different possibilities. It does not normalize students, but it does allow them to find their own way of participating. For Katz (2013), the UDL is an instructional approach that promotes access, participation, and progress for all students in the curriculum. Thus, it recognizes the need to create different learning opportunities and therefore different participation possibilities in a single curriculum. The principle of schooling focused here for people with disabilities is the learning of all students, with disabilities and without disabilities, with responsive educational actions, considering variability in the way of learning, since disability is a human condition (Bock et al. 2018). In this perspective, the idea is to customize the learning of all students, to offer the opportunity to construct what is possible regarding inclusion as a right of all human beings.

Cha and Ahn (2014) also mention the effectiveness of UDL, when addressing the use of tools/artifacts in inclusive classes, inspired by historical-cultural theory. The authors address the importance of cultural artifacts (physical or abstract) and of systematic tensions for learning. Historical-cultural theory, with Vygotsky (see chapter ► “The Possible in the Life and Work of Lev Vygotsky”) as one of its main representatives, brings important substance for thinking about the learning process and the development of students with disabilities. The centrality of this author’s theory lies in the understanding of language as a symbolic (abstract) cultural artifact, as

constitutive of the human being, of his/her inner world, as an instrument of thought (Vygotsky 1993, 2001).

The Centrality of Language in the Constitution of Humankind

In criticizing the medical model of disability, which pathologizes the subject with disabilities, Vygotsky (1997) brings subsidies to build a path for what is possible with regards to inclusion. For this, the intention here is to have a wide discussion on the concepts of primary disability (organic impairment), secondary disability (social conditions), and social compensation processes as the only scientifically valid path for the learning and development of people with disabilities, and the emphatic defense that these can occur through language and internalization processes. In this paradigm, mediation is a central point and its focus is on the presence of cultural artifacts – mainly language – as elements that bring complexity to the relationships between the organism and the environment, allowing individuals to internalize and elaborate meanings, and build their own representations of the world. For this author (Vygotsky 1997), a primary (biological) disability modifies the relationship between a human being and the world, but the laws of development will be the same for anyone, with or without disabilities. What will differ is the path of insertion of the subject in the world, the people with disabilities traversing different pathways, translating into the different possibilities of inclusion. He mentions that from a psychological and pedagogical point of view, the conduct of the person with a disability can be completely equated with that of the nondisabled.

An important question that can be related to the concepts of primary/biological deficiency and secondary/social deficiency (Vygotsky 1997) is the reference from historical-cultural theory about the development of the human baby when compared to other nonhuman animals. Pino (2005), corroborating Vygotsky's position, when addressing the evolutionary advantage of Homo sapiens, mentions that what distinguishes human

beings from other animals are the superior psychological functions, of a cultural nature, particularly language. The fact that the human baby needs to be cared for reinforces the role of the cultural experience in "becoming a human being" (Pino 2005, p. 46). In relation to this point, the development of human beings with and without disabilities goes beyond the biological dimension and occurs at the cultural level, differing greatly from other animals. Thus, from a psychological and educational point of view, the sociocultural development of children with disabilities cannot be denied when subjected to spaces and activities that do not affect higher psychological functions. All people need to be inserted in the human environment, with all the implications of this insertion, which points to the idea of the possible with regards to inclusion even when exclusion emerges from human culture itself.

Pino (2005) takes up the Vygotskian idea that there is a kind of transposition from the collective/cultural experience to the individual experience, which occurs through mediation and which is in the order of meaning. Thus, language plays a central role in the internalization process, and in this sense it gains the status of an instrument of thought. In this relationship between thought and language, the child goes from a phase in which the language is purely emotional to an objective language (with communicative intentionality). Vygotsky (2001) argues that "language is not only a means of expressive-emotional articulation, but also a means of psychological contact with similars" (p. 127). Allowing people with disabilities to access forms of abstraction from an early age is to allow them to develop meaning and insertion into culture, even if they use other forms of language besides speech. Although it may already be understood at this point in the text, it is necessary to point out clearly that the terms "speech," "word," and "voice" hereby utilized dispense at all times of any need of association with sound, as they are meant to be understood within a much broader idea of language, one that gives meaning to the human being in his/her communication with the world, whatever its peculiarity. A person communicates with the world from sound language, and also

with the language of gesture, drawing, and looking. Hence, “the space of the word” here is the space granted for individuals to constitute themselves in an intersubjective manner, in all its idiosyncrasy, as individuals and citizens. Moreover, the main thesis defended here is that there is a privileged discursive space in which this movement of the intersubjective constitution of the individual and his/her social inclusion happens: the discursive space of argumentation.

The Possible of Inclusion By Way of Argumentation

The whole concept of Vygotskian language presented here is precisely what supports the idea of the possible, proposed in this text. When language is understood as part of the psychological makeup of a human being, from an internalization process that takes place within a space of intersubjectivity, the importance of the “space of the word” is defended as a means for the participation, transformation, construction, and affirmation of identity, empowerment, and, consequently, the exercise of citizenship and social inclusion of the disabled person. However, among the countless possible discursive organizations, this text proposes that it is the discursive organization of argumentation itself that is the privileged locus of discourse where inclusion is enabled. The historical review presented here on the relationship of humanity with the issue of disability denoted the silencing of these individuals, the restriction of their voice spaces, the barriers imposed on them in their formation as individuals and citizens, and, consequently, their exclusion. Thus, the intention here is to clarify the direction this argumentation can take, as a path to rescue this “space of the word” for these people, and as a process of social compensation that drives the movement of inclusion.

Among the different perspectives from which argumentation can be observed according to their philosophical affiliations, the understanding here is of a discursive activity that is unveiled when at a given moment, in response or in anticipation of an opinion, a different opinion is constructed, and

from a dialogical course (see chapter ► “[Dialogism](#)”) both sides try to justify their positions, seeking to make them increasingly acceptable to their interlocutor (van Eemeren et al. 1996; van Eemeren et al. 2014). The dialogic term used here goes beyond the understanding of dialogue most used in the common sense to refer to interactional communication between people in a synchronous way in time and space. Here, dialogic refers to Bakhtinian dialogism (see chapter ► “[The Possible in the Life and Work of Mikhail M. Bakhtin](#)”). Bakhtin (2005) understands dialogical relations from beyond their face-to-face interaction, as a dialogue among different voices in a universal symposium, which may have been constituted at different times and spaces, not necessarily synchronous, but which bring multiple perspectives that intertwine and respond to each other. In this sense, it is possible to understand that the existence of a dialogue does not require the presence of two or more people, which can happen, for example, within a single statement as long as it is possible to recognize different perspectives in a symposium of voices that diverge dialogically. And within this perspective, any statement emerges from a social context of meanings and values, portraying the dialogical subjects are constituted by sociocultural voices that make them historical and social beings, but also particular and unique, since even in the assimilation of other voices, the dialogic subject, never passive, re-signifies them, accentuating their “saying” in a unique manner (Bakhtin and Voloshinov 1995). According to Cavalcante (2017), from this understanding of the dialogical subject, the person with disabilities is also constituted within this relationship between historicity and singularity. For the author: “It is in this social place that, it is believed, all people must constitute themselves” (p. 429).

The importance of this understanding of dialogue, which is at the basis of the argumentation perspective proposed here as a possible path for social inclusion of people with disabilities, is that it authorizes the perception of the responsive character the subject assumes in a situation of argumentative dialogue, whether he/she is with an interlocutor present synchronously or simply assumed. The focus of attention falls on the fact

that, for those who practice it, argumentation provides opportunities – alone from his/her dialogue of inner voices, or collectively, constantly led to and immersed in a specific historical and cultural context – to position themselves and build their perceptions about the world, defending them in face of the possible presence of different perspectives. This movement, therefore, contributes for individuals to build their personal identities and assert them in their social space. For those who carry a history of marked silences, as is the case with people with disabilities, the encouragement to engage in dialogue in which their position in the world is not only enabled but requested and stimulated appears as an alternative of social compensation that envisions constituting an interesting path to the achievement of citizenship and inclusion. Thus, this constitutes a possible path for the empowerment of these people, due to the great potential for transformation that it holds regarding equality of conditions, allowing them to exercise power over themselves and over their social condition.

The peculiarity of the argumentative dialogue that makes it significant in this sense can be more clearly perceived when looking at the two movements highlighted by Leitão (2000, 2011), which specify and define argumentation, namely: the justification and the negotiation of meanings. When an individual is asked to take a stand on a subject, a point of view is constructed and proposed by him/her and one or more justifications are usually added. These may come spontaneously or be demanded by the interlocutors (present or imagined). The justification, according to the author, demands from this proponent a movement to think about the bases that support his/her thinking on the subject in question, in order to make his/her point of view more acceptable. Similarly, this thinking about your own thoughts also occurs when an opponent demands (in person or when an opposition voice is anticipated) an answer to your different position on the same question. At this point, the proponent is also led to put his/her own thoughts under review and reflect this time on the limits that surround his/her position. This critical and reflective movement provides the opportunity for a new discursive

construction that will have an impact on this individual's thinking on the issue.

Two points are important to highlight. The first is that in both cases the individual was led from a cognitive functioning, in which the central focus was to think about the subject in question, to a metacognitive and self-regulating functioning, in which the focus became his/her own thoughts about the subject in question, which allows us to denote the potential of this discursive activity in developing reasoning skills. The second point is that within the dialogical dimension that defines the argumentation assumed here, proponent and opponent can exist in the same person as voices that negotiate intrapsychologically, for example, a simple decision of someone's day-to-day life, without the need of emitting any one sound. This directly affects the possibility of using argumentation with people with different types of disabilities, since it can occur at very different levels of depth, from day-to-day topics to scientific questions – and also in the most varied forms, verbalized or not, using writing or not, involving movements or not, and even in the most different configurations in tasks performed by an individual alone, in pairs, or in groups. In all cases, what is defended here is that this argumentative function will be helping the individual to constitute himself as a person in the world, with opinions, positions, identity, and helping him/her to advance in this spectrum from exclusion to inclusion.

Two studies deserve to be cited as examples of the scope that the use of argumentation with people with disabilities can have. In Cavalcante and De Chiaro (2011), the authors bring contributions to the reflection on the process of school inclusion of students with Down syndrome. This study shows how the argumentative discourse in the classroom can encourage and impel communicative movements and favor the construction of knowledge of a child with Down syndrome, in participation with the other students without disabilities in the third year of elementary school. Pereira's study (2017) aimed to analyze the contributions of argumentation in the teaching of Chemistry, in a class on radioactivity, with deaf students who use Libras (Brazilian sign language). The results showed signs of skills

development in understanding the content and in recognizing the ethical and moral limits in dealing with radioactivity by deaf students. In both cases, the activities took place from the emergence of situations of argumentation mediated by the argumentative discursive actions intentionally implemented by the teachers (De Chiaro and Leitão 2005; Leitão 2011).

It is necessary to highlight that to have argumentation here as the possible of the inclusion process meant drawing attention to something that precedes the consideration of its potential, for the construction of critical and reflective knowledge and the development of reasoning skills. Just as important, especially when referring to people with disabilities, is the impact argumentation has on the constitution of personal identities and the acquisition of social space, providing that this exclusion–inclusion tension can be interpreted within the idea of a possible overcoming, via argumentation.

Conclusion

To what extent the “space of the word” can become an instrument of social exclusion or inclusion is raised here from a reflection on how a discursive organization, which has the peculiarity of taking those who exercise it to an inevitable position in the world, can become a fruitful path towards inclusion. The idea of argumentation as the possible of inclusion is based on its dialogical dimension in which the individual is constituted in an intersubjective manner, that is, one sees and recognizes oneself through the other, whether real or imaginary. Within this perspective, when arguing, there is a multiplicity of voices to which the individual projects him/herself in such a way that one cannot think of a self alone, because whether or not one is physically with someone, there is always a multiplicity of voices with whom one dialogues, constituting oneself as a historical and unique being. The responsive character of the argumentation itself gives the opportunity for this historical and unique individual to position him/herself, to assert him/herself as a person who is a citizen and thus moves towards social inclusion. The more specific

intention of placing people with disabilities as the focus of these reflections was to point out how individuals with a history of silencing of their voices, of restriction of their speech spaces and who live to this day in a constant struggle to be recognized as individuals and citizens, can find in argumentation a possible path for the participation, transformation, and empowerment toward social inclusion. Inserting people with disabilities in social spaces does not guarantee that they are, in fact, included, since inclusion depends not on the order of physical space but the symbolic, the subjective. Physical presence, when not well mediated, can mean the creation of an apparent atmosphere of inclusion that, on the contrary, accentuates exclusion. For this reason, this text defends the importance of thinking about the inclusion of people with disabilities beyond the physical space, in the “space of the word,” proposing finally that the place of symbolic affirmation created by argumentation can compensate for what the physical place does not ensure.

Innovation

Lionel Artige

University of Liège, Liège, Belgium

Abstract

Innovation is the human capacity to give an idea the power to change the course of events and to push back the frontiers of the possible. If innovation is nowadays praised in the West and even beyond, it has long had a negative connotation in a semantic field limited to politics and religion. It is with the Enlightenment and the faith in the progress of the human condition that innovation, instrument of disruptive change, takes on a positive meaning. Its semantic field then widens to other domains such as science, arts or society before the word “innovation” becomes an essential concept in economics, the creative force that the economic system generates and that transforms it. This belated confidence in the beneficial effects of innovation may have reached its limits with the ecological crisis.

Keywords

Creative destruction · Creativity · Innovation · Possible · Transformative creation

According to a quote attributed to the French poet Paul Éluard, “un autre monde est possible, mais il est dans celui-ci.” [Another world is possible, but it is in this one.] The human imagination may have no boundaries, but our physical world is finite.

Innovation is this human capacity to give an idea the power to change the course of events and to push back the frontiers of the possible at the risk that this power spins out of control and ends up annihilating everything. If the spirit of innovation is nowadays acclaimed and promoted in all Western societies and even beyond, this spirit has long been considered throughout history as harmful or even dangerous. This belated confidence in the beneficial effects of innovation may have reached its limits with the ecological crisis.

Definition Through History

Changing the status quo involves an uncertainty that can provoke two reactions: hope and fear. Hope that a better future is possible or fear of losing the stability of a known present. Innovation as the introduction of novelty into the status quo can have a negative meaning when tradition and stability are highly valued and can have a positive meaning when people are confident in their ability to think and act to change the world for the better. Historically, the word “innovation” shifted from a negative to a positive meaning during the scientific, political, and industrial revolutions when elites and people became convinced that tradition was the obstacle to progress.

Etymologically, the word “innovation” goes back to the Greek word *kainotomia* (from *kainos*: new) which becomes in Latin *innovatus*, past participle of *innovare*, itself derived from the Latin word *novus* which means “new.” *Innovare* means “to introduce something new,” “to modify,” “to renew,” or “to restore” (Oxford Latin Dictionary; Godin and Lucier 2012). The etymology tends to suggest that innovation is the origin of something or the return to that origin.

Based on a careful reading of numerous texts, Godin (2015) traces the history of the word “innovation” and its meanings from Antiquity to the present day. He observes that the word has a predominantly negative meaning from Antiquity until the eighteenth century and that it is used exclusively in the political and religious domains. In Ancient Greece, innovation (*kainotomia*) is seen as a change initiated by humans that disrupts the divine and natural order of things. For

Aristotle, for example, innovators are people who seek to change the political order for private ends. Innovation is therefore political and subversive. It threatens the stability of the political order. Laws can be changed, of course, but carefully and gradually, whereas *kainotomia* is a disruptive change often translated as “revolution.” This political and subversive connotation can be found in Ancient Rome, where the stability of the political order remains a social goal. But when Christianity becomes the official religion of the Roman Empire in the fourth century, innovation (*innovo*) also takes on a religious connotation and describes the spiritual renewing to which Christians are called in order to rid themselves of their old corrupted nature and to transform themselves into new people created in the image of God. Thus, innovation as a spiritual and moral renewing acquired a positive meaning that it would retain until the Protestant Reformation. In the England of the sixteenth and seventeenth centuries, innovation recovers its subversive and pejorative connotation from Antiquity. Protestants and Papists accuse each other of being “innovators.” The Catholics consider the Protestants as heretics because their innovations lead to the creation of a new church. The Protestants retort that they want to create a reformed church in order to return to the original church, which the Catholics, by their innovations, have corrupted. Religious doctrinal innovation represented such a religious and political threat that in 1548 Edward VI, King of England, issued *A Proclamation Against Those that Doeth Innovate* and threatened the innovators with “*imprisonment, and other grievous punishments*.” In 1626, King Charles I reiterated the prohibition of innovation. But who was concerned by this prohibition? For the Protestants, the Papists were guilty of having innovated since the origins of Christianity. For the Papists, the Protestants were guilty of having innovated since the Reformation. For the Puritans, the English Protestants were guilty of having kept certain Catholic innovations in the Reformed Church. Finally, everyone was an innovator! This is the logical impasse that Bentham (1824, p. 144) will later point out: “Whatever is now *establishment* was once innovation.” King Charles I was also accused of innovating in

religious and political matters. From the seventeenth to the nineteenth century, the established order in science and politics wavers. The past is less venerated and even contested while the future gives a glimpse of hope for progress. The revolutionaries are accused of being innovators by the supporters of the established order, but the state of mind in Europe begins to shift toward a spirit of innovation. Gradually, innovation ceases to be a source of fear and becomes an instrument of progress of the human condition.

From the Word to the Concept

In the nineteenth century, innovation becomes a virtue in the name of faith in scientific progress and its expected positive effects on living conditions (Godin 2015). The word “innovation” is no longer confined to politics and religion but extends its semantic field to the scientific, artistic, and social domains. Innovation is then both the introduction of a novelty in all these domains and the consequences (change) resulting from this novelty which can be an invention or more broadly a creative idea. Innovation is “iconoclast, divergent, revolutionary thinking” (Kuhn 1959) and the change resulting from innovation has an economic value which increased with the takeoff of economic growth in Europe following the Industrial Revolution. An invention or creative idea can exist without having a market value. Not innovation, which always has economic consequences. It is because change has economic implications that innovation has an inescapable economic dimension. With economic growth, this economic dimension will become central in the twentieth century and even reduce the meaning of innovation to its sole economic dimension. An invention or a creative idea that is not introduced to the market is not an innovation. The novelty becomes an innovation as soon as it acquires a market value and modifies the available supply on the market. This is the meaning that the twentieth century gives to innovation. Of course, the term “innovation” continues to be used in other fields than the economy but always followed by the adjective designating the field:

technological, artistic, political, or social innovation. When the term is used alone, it is an economic concept.

In the scientific literature and the media after the Second World War, innovation often has a technological dimension. But for the last two or three decades, undoubtedly influenced by the rise of the concept of “creativity” in psychology and then in economics, the concept of innovation has broadened its semantic field to mean the commercialization of any creative idea (Artige and Lubart 2020). A representative definition of innovation in contemporary economic literature is as follows:

Innovation can be defined as the application of new ideas to the products, processes, or other aspects of the activities of a firm that lead to increased “value”. (Greenhalgh and Rogers (2010), p. 4)

This “value” is defined in a broad sense to include the higher value added gained by the innovative firm but also the benefits to consumers (higher utility) or to the firms that buy the innovation (higher value added). All economic agents – households, firms, NGOs and public administrations – can introduce innovations. Nevertheless, from the point of view of economic change induced by innovations, it is the innovations made by firms that have the greatest impact.

Innovation: The Engine of Economic Development

Innovation is widely regarded by contemporary economists as the main driver of growth in living standards. This has not always been the case. It was not until the first half of the twentieth century and the pioneering writings of the Austrian-born American economist Joseph Schumpeter that innovation was considered a central economic concept in economics. Although he was a professor at Harvard University from 1932 until his death in 1950, Schumpeter’s work was long labeled as heterodox by his peers and therefore had limited influence on mainstream economics until recently. This was not the right time for his work to attract interest. His contemporaries were preoccupied with the traumas of the crisis of the 1930s and the Second World War. Keynesian

demand-side solutions met the expectations of economists and governments seeking to pull Western economies out of the economic slump, thus overshadowing the Schumpeterian supply-side analyses of capitalism. The work of Robert Solow (1956, 1957) at the end of the 1950s, which highlighted the role of technological progress in economic growth, led to a reorientation of research toward innovation and, consequently, toward the pioneering work of Schumpeter. The supply-side economic crisis of the 1970s and the ensuing decline in productivity in Western countries accentuated this scientific shift and allowed the Schumpeterian approach to enter the mainstream of economics (Giersch 1984) and to inspire the first Schumpeterian growth models (Aghion and Howitt 1992; Klette and Kortum 2004).

Schumpeter praised the systemic approach used by Léon Walras, the father of the neoclassical theory of general market equilibrium, whose objective was to determine the equilibrium conditions for the allocation of scarce resources in perfectly competitive markets. However, no doubt influenced by the more historical approaches of Adam Smith or Karl Marx, he considered that the market mechanics of the neoclassicals completely missed the point of how market economies work. While he recognized that price competition between firms leads to an efficient market equilibrium, he stressed that this equilibrium was static and efficiency was limited to the short run. However, observation of the history of Western economies since the Industrial Revolution shows that the characteristic of market economies is their incessant dynamics of change. There is, Schumpeter argues, a “source of energy within the economic system” that deviates it from its static equilibrium of perfect competition (Schumpeter 1937). This “source of energy” is none other than innovation. Driven by a profit objective, firms compete not only by price but also by innovations that distinguish them from their competitors and allow them to reap temporary monopoly rents (deviations from perfect competition), that is, the entrepreneur’s profit. Neither neoclassical, nor Marxist, nor Keynesian, but inspired by many, Schumpeter proposed, at a time when the market economy was experiencing

its deepest depression, an original theory of economic development where innovations sacrifice short-term static efficiency (the profit from the innovation is a loss for the consumer but an income that finances the innovator’s research and development costs) to create long-term economic growth (innovations create productivity gains that raise material living standards).

Transformative Creation Rather than “Creative Destruction”

Economic development fueled by innovation-based competition is not a smooth evolutionary process. Schumpeter (1942) calls this process “*creative destruction*.” Innovations create new activities and jobs but also destroy existing activities and jobs. As the budget of consumers is limited, there is no room for all firms (existing and new) on the markets. This is why innovative firms that gain market share drive those that are not innovative enough out of business. In other words, innovations create winners and losers: firms are born and others go bankrupt; workers find or change jobs and others lose theirs. At the macroeconomic level, innovations have a positive net social effect if and only if the value created by the innovations outweighs the value destroyed. Competitive pressure ensures that this is the case, since firms that survive competition are necessarily more profitable than firms that disappear. This cycle of creation and destruction of activities is a process of selection of the firms best able to respond to demand or to generate it. The innovations brought about by these firms make it possible to create a long-term growth process accompanied by structural change due to the different growth rates across sectors of activity. It is not the random effect of multiple external causes but the economic system itself that “generates the force that incessantly transforms it” (Schumpeter 1937). This dynamic economic process makes it clear that the concept of “*creative destruction*” is a misnomer. The destruction of activities does not create new ones. It is the creation of activities that both creates and destroys value and leads to the transformation of the supply of goods and services over time. At the origin of this process, there are creative ideas that penetrate markets and disrupt

Innovation, Fig. 1 The genealogy of innovation

the existing supply and demand by proposing a competitive innovative supply. By constantly stimulating demand, innovations put pressure on the existing supply, which is forced to innovate in turn or exit the market. This incessant pressure contributes to both a quantitative increase in the value created and a qualitative change in what is produced and sold in the economy. The successive waves of innovation thus generate a process of *transformative creation* of the economy (Fig. 1).

The Existence Conditions of Innovation

The process of transformative creation is based on the production of creative ideas, some of which will become innovations introduced on the market. The production of these ideas and the development of innovations have an economic cost that the innovator is willing to pay if the profit she can expect covers at least this cost. However, this is not guaranteed for several reasons. First, the search for a creative idea is an uncertain process that often requires a research expenditure. If the search is successful, the creative idea can lead to two opposite economic situations. If the author of the creative idea manages to keep it secret, she can incur expenses to develop an innovation that she alone will be able to supply on the market. This situation is the best for the innovator since the monopoly allows her to set the price at a level sufficient to refund the cost of research and

development of her innovation. The opposite situation occurs if the creative idea is publicly disclosed for some reason. Once public, the creative idea is a public good, that is, it is a nonrival good (many people can use the idea at the same time) and a non-excludable good (it is difficult to prevent others from using the idea). When the creative idea becomes public, its author loses the monopoly on it and, most likely, on the innovation that will be supplied on the market. The more people who sell the innovation, the lower the market price and the lower the profit. Of all the sellers, it is the author of the creative idea who loses out, since it was she who financed the initial research. Arrow (1962) argues that the disclosure risk borne by the innovator discourages innovation and leads to a suboptimal production of creative ideas. In a market economy, the optimal consumption and the optimal production of an innovation resulting from a creative idea are incompatible. The optimal consumption of the innovation requires the lowest possible price, that is, a price equal to its marginal production cost (zero profit), which would result in a loss for the innovator (the profit does not cover the research and development costs). The optimal production of the innovation requires a profit high enough to cover the initial research and development costs, which is possible if the creative idea is not made public. In this case, the innovator can sell her innovation at a monopoly price, that is, at a price higher than the marginal

production cost. While this price is optimal for the producer of the innovation, it is not optimal for the consumer. This incompatibility is what economists call a market failure. If the author of a creative idea (e.g., a new vaccine) cannot appropriate the economic benefit of her idea because of its public disclosure, then she has no economic incentive to seek and develop a creative idea and then an innovation. Conversely, if the author of a creative idea (the new vaccine) has exclusive ownership forever of the economic benefit of her innovation, then the monopoly price will restrict access to the new vaccine, and the exclusive ownership of the idea will prevent others from using it to create new ones. Creative ideas grow out of each other. It is therefore useful that they can spread and be used by others. In order to solve this dilemma, the institutional solution that has been found, at least in Western societies, grants legal protection (patents, copyrights, etc.) to the creators of ideas and, in exchange for the public disclosure of the ideas, requires producers who would like to use them to pay royalties to the authors. This solution aims at combining the creation of guaranteed rewards for the production of creative ideas and their wide dissemination for optimal use. The system is not perfect, but it does break the trap of market incentives for creative ideas. It also highlights that the innovation-based economic development requires a sound institutional architecture and respect for rights such as intellectual property rights.

Innovation and the Possible

Figure 1 represents the genealogy of innovation from its human brain origin to its macroeconomic effects. Creative ideas can be stimulated by necessity (finding the vaccine for a pandemic; adapting to climate change), needs or desires, (intentional) imagination, unintentional inspiration from life experiences or knowledge, potential economic benefit, or a combination of these different stimuli. Ideas are not made, they come to our mind. A creative idea is thinking about something that does not exist and that begins to exist (the abstract

possible). Once expressed, creative ideas are added to the existing stock of knowledge and push back the (a priori infinite) limits of the abstract possible. Freedom of thought, the stock of knowledge, a creativity-friendly culture, technologies for the dissemination of ideas, and potential economic benefits can explain the quantity but also the quality of creative ideas expressed and thus made public. Some of these creative ideas may be in demand from individuals and firms, creating a market and selling prices. Then, they may turn into innovations (the real possible) and feed the transformative creation process. As soon as human creativity is unleashed or even promoted, the abstract possible generates the real possible under the constraints of feasibility, physical and financial resources, and consumer demand. The question is then: does the real possible accomplish the progress of the human condition promised by the Enlightenment? In a democratic market economy, the economic system is decentralized: the real possible is the aggregation of a multitude of decisions made by individuals free to think, create, and innovate. There is therefore no central command to set its destination, control its trajectory, and modulate its speed of evolution. However, the finitude of Earth does not guarantee the sustainability of any real possible. Figure 2 characterizes the trilemma facing the humankind: unlimited growth in income per capita and in population is incompatible with the limited amount of exhaustible natural resources essential to life. Therefore, the trajectory of our real possible that originated at the time of the Industrial Revolution is unsustainable. The humankind has been slow to become aware of this sustainability constraint. We can only hope that this constraint inspires the abstract possible in order to redirect the real possible in time.

Conclusion

Innovation is today an economic concept and a state of mind that is praised at least in Western societies. Until the eighteenth century, the semantic field was restricted to the political and religious fields and its

Innovation, Fig. 2 The trilemma of humankind. (Per capita income growth, population growth, and sustainable consumption of natural resources may be three desirable goals for a society. Unfortunately, these three goals are not achievable simultaneously. Society must therefore make a choice by eliminating one of these three goals. The goal

that humankind is currently sacrificing is the sustainable consumption of natural resources for the other two. Given the environmental disruption that unreasonable consumption of these natural resources causes, this choice leads to a dead end in the medium or long term for life on earth.)

connotation was negative. The change took place with the Enlightenment and the new faith in the progress of the human condition. Innovation then became the instrument of disruptive change in the political, scientific, artistic, and social fields. The economic growth resulting from industrial change during the nineteenth century highlighted the economic effects of innovation, which became one of the fundamental concepts of economics in the twentieth century. At the origin of innovation is creativity, a human ability to push back the limits of the possible. This force capable of transforming the economic system and the condition of humanity is little controlled in a decentralized market economy. The current trajectory of this force is physically unsustainable and therefore poses a risk to the future of humanity. It is up to mankind to prove that in this world, another is indeed possible.

University, Kingston-upon-Thames, UK

Abstract

Insight is a form of comprehension that results in the connection between two hitherto unappreciated, unacknowledged, or simply unknown ideas and, consequently, expands the realm of the possible. Making these connections is a powerful driver of creativity and innovation. As a putative cognitive process, insight has exercised psychological researchers for over 100 years. Efforts to capture insight under laboratory conditions are constrained by exigencies of operationalization and control, as well as by an implicit ontological position that casts insight as a property of the brain. As a result, psychological research has focused on what we term second-order problem-solving, which is reasoning triggered by problems presented as propositions that describe states of the world. People are tasked with finding new connections among the problem elements, but these connections can only be made by manipulating a mental representation of the problem. Creative cognition outside the psychologist's laboratory involves a great deal of interaction with the world. In contrast to second-order problem-solving, first-order problem-solving characterizes activities of embodied agents as they interact and manipulate the world around them. Creativity and insight emerge through a transactional process of transformation: physical features cue actions that change both the reasoner and the physical environment in which he or she is embedded. Insightful new possibles are realized through an active and mutually transforming exploration of the problem-solving environment. We discuss insight as an enacted process, involving action and perception. As a physical and perceptual

activity, a degree of serendipity is inevitable, and, in some circumstances, insight becomes "outsight." We identify eight key features of first-order creative cognition that map out a new program of research on insight.

Keywords

Creative cognition · First-order problem-solving · Interactivism · Systemic thinking · Material engagement

Insight, as the word and its etymological origins suggest, is a form of inner sight. There is an interesting tension in the juxtaposition of inner and sight: it is something that happens within a private and subjective world, yet it involves "seeing," a perceptual activity aimed at the outer physical environment, rather than the inner, psychological one. There is something quite interesting about the embodiment of many metaphorical expressions (Gibbs Jr. et al. 2004), and we will return to this perceptual element of insight (and suggest a new twist on an old term).

Insight is a form of comprehension that results in the connection between two hitherto unappreciated, unacknowledged, or simply unknown ideas. Insight is thus a form of creativity, a type of discovery of a new possible. The insightful understanding can be expressed as a new proposition and hence can be assigned a truth-value (Bickhard 2009). The phenomenological signature of this type of inference (Bowden and Grunewald 2018) and its coordinates of occurrence (Ovington et al. 2015) have led to the following observations: Insight can be sudden, it can be accompanied by a positive emotion, and it is sometimes experienced in prosaic quotidian activities (e.g., while bathing). These features have encouraged some researchers to conceive insight as a phenomenon largely driven by unconscious processes. For example, Ohlsson (e.g., Ohlsson 2018) conjectures that patterns of activation in semantic memory may result in the connection among disparate elements; when these associative connections reach a certain level of activation, they become consciously accessible, and a new idea is born.

Historical and retrospective accounts often cast the experience of insight as a pivotal moment in problem-solving, a consequential inflection point in conceptualization that ushers in a significant breakthrough in design, science, and art. Weisberg (2010, 2018) reviewed a number of these moments, including Frank Lloyd Wright's design of Fallingwater, Wilkins's invention of radar, and da Vinci's design for the aerial screw. Whether these moments actually resulted from an experience of insight, with a distinctive phenomenological signature and unconscious origin, is debatable. The debate is partly fueled by the unreliability and circumstantial character of these historical reconstructions and by plausible alternative explanations in terms of deliberate analysis and analogical reasoning that promoted the gradual rather than sudden reorganization of knowledge.

Insight in the Laboratory

Insight can be studied under laboratory conditions. Researchers present participants with a problem, the solution to which resists the direct and effortless application of long-term memory knowledge. For example, neuroscience researchers use remote associate problems that consist of three words – e.g., “blue,” “cottage,” and “cake” – and participants' goal is to find a word that could be associated to each three to produce a meaningful combination (Kounios and Beeman 2014). Participants who answer “cheese” are then asked to indicate whether they experienced the solution as an insightful one (using Likert-scale ratings on dimensions such as suddenness, pleasantness) or as the product of an effortful analysis of the words and their possible connection. Insightful answers are more likely to be associated with neural activation in the right temporal lobe. Researchers attribute this hemispheric asymmetry to the right hemisphere's relatively coarser semantic coding, which results in broader more diffuse activation of semantic elements (Kounios and Beeman 2014).

Other researchers have employed so-called “insight” problems (Weisberg 1995; Webb et al.

2018). Such problems are designed to encourage a misleading initial interpretation. Take for example: How do you place 17 animals in 4 enclosures such that there is an odd number of animals in each enclosure (Vallée-Tourangeau et al. 2016)? The problem masquerades as a simple arithmetic one, and indeed participants initially engage in a fruitless search for 4 odd numbers that can add up to 17. Thus, the initial interpretation inexorably leads to an impasse: the state that insight problems are designed to produce. These problems offer a strategic window through which researchers can observe how the impasse is overcome and a breakthrough experienced. In the case of the 17 animals problem (see Fig. 1), participants must shift the focus of their efforts and seek to exploit set overlaps, double counting at least one animal.

Insight coincides with a conceptual restructuring. Drawing from Gestalt ideas, Ohlsson (1992) proposed that representational change is achieved when the conceptual elements of a problem cohere in a new gestalt, from which the solution to the problem is more clearly anticipated in the participant's mental look ahead the horizon. Thus, in the 17 animals problem, representational restructuring involves casting overlapping sets as the key to the solution, and once this is achieved, the solution can be crafted. The question that animates psychologists at this juncture is what drives the experience of insight in such circumstances; in other words, how do people manage to restructure their representation of the problem so that they clearly appreciate the fruitlessness of their initial

Insight, Fig. 1. A possible solution to the 17 animals problem (Adapted from Vallée-Tourangeau et al. 2016)

interpretation? What brings about a new more fruitful interpretation?

Different answers to these questions are proposed by competing perspectives. The special processes view (e.g., Ohlsson 2018) casts restructuring in terms of unconscious semantic inferences. In turn, the business-as-usual view (e.g., Weisberg 2018) proposes that restructuring is evidenced through the deliberate, conscious, and effortful analysis of the problem elements. The main research strategy employed to adjudicate these proposals involves profiling participants in terms of their cognitive capacities, such as their working memory capacity. Working memory corresponds to a limited-capacity system and range of processes that support the temporary storage and conscious manipulation of information (Baddeley 2012). Researchers then determine the degree of correlation between scores on these measures with performance on insight problems. If insight is the product of unconscious semantic inferences, then working memory capacity should explain little variance in problem-solving performance. In turn, if insight is the product of deliberate analysis, then measures of working memory capacity should correlate strongly with performance. Recent evidence appears to endorse the business-as-usual camp (Chuderski and Jastrzębski 2018), but the debate is far from resolved (DeCaro 2018).

First-Order Problem-Solving and Interactivity

Let us pause and reflect on the research methodology employed by psychologists to measure insight and the cognitive processes that promote it. Laboratory work inevitably involves scaling down complex phenomena in terms of essential components amenable to operationalization and experimental manipulation. Thus, laboratory participants are presented with a set of propositions that describe, ambiguously, some complex states of an abstract world. Problem-solving and hence insight are therefore also constrained to take place in a virtual world simulated internally in the mind. No matter how dynamic the debate between the

special processes and business-as-usual camps, the research methodology constrains the nature of the explanation for insight.

Creative problem-solving outside the psychologist's laboratory proceeds in a very different manner and calls upon researchers to question their ontological assumptions and methodological prescriptions. Clearly, professional artists, designers, and engineers have a different occupational trajectory and a level of expertise that make them different from the naïve participants in a psychologist's experiment, working on a so-called knowledge-lean problem. More important, insight can be considered as an enacted phenomenon (e.g., Henok et al. 2018), that is, it manifests through physical actions with and through the world within which a reasoning agent is embedded. Some problem-solving researchers have paid insufficient attention to the interactive nature of thinking, focusing rather on what has been termed second-order problem-solving (Vallée-Tourangeau and March 2019), that is, problem-solving that proceeds from abstract descriptions of states of the world and must inevitably involve changes in mental representations. In contrast, first-order problem-solving proceeds through the active manipulation of a physical model of the problem. Take the 17 animals problem again. When participants are invited to solve the problem by building a physical model of a solution – using pipe cleaning pieces and animal figurines – they are more likely to derive a correct solution compared to participants who are asked to sketch a solution of the problem (Vallée-Tourangeau et al. 2016). Interactivity is an ontological substrate (Steffensen 2017) from which new ideas arise. Casting insight as the product of first-order problem-solving activity identifies a much broader range of important features of creativity and discovery and opens up the field of enquiry beyond the confines of the current debate in cognitive psychology. We limit our discussion here to eight features of first-order problem-solving that have not been considered in current models of insight.

1. **External Storage.** Working with a physical model of a problem reduces the need to

mentally represent the problem. The world is its own best model (to adapt Brooks 1990), and there is no need to represent it, or to mentally manipulate these mental representations, or to rehearse and store these representations. The world is there to see and act upon. Expanding storage frees internal cognitive resources and reduces working memory burden (Vallée-Tourangeau et al. 2016; Vallée-Tourangeau and Vallée-Tourangeau [Under Review](#)) resulting in more flexible reasoning.

2. **Boundary Objects.** Interim solutions, proto models, and sketches are transactive memory objects (Fiore and Wiltshire 2016) that bridge the past to future possibilities. Creative problem-solving and the occurrence of an “insight” occur along a trajectory dotted with such boundary objects.
3. **Unfolding and Undergoing.** Problem-solving is a transformative activity. The reasoner at time 1 is not the same reasoner at the time of the solution. He or she has been transformed by the proto-solutions formulated in the process of arriving at a satisfactory or correct solution. This process of transformation is shaped contingently by the intermediary steps to a solution. Insight reflects a transformation (Ingold 2014; Glăveanu et al. 2013; Vallée-Tourangeau and Vallée-Tourangeau 2014a).
4. **Serendipity.** When thinking with and through the world, the construction and manipulation of a physical model of the problem can capitalize on felicitous but unplanned results. Serendipity plays a role for large and small discoveries (Copeland 2019); so-called strong serendipity in science involves discovering something completely unexpected (Alcock 2010). A weaker form of serendipity is observed in insight problem-solving when the task environment supports the interaction between an agent and a physical model of the problem (e.g., Fioratou and Cowley 2009), and fortuitous configurations can exert a significant influence on the problem-solving trajectory (Steffensen et al. 2016; Ross [Forthcoming](#); Ross and Vallée-Tourangeau 2020).
5. **Moving Fast, Thinking Slow (Polytemporality).** Processes operating at different time scales are involved when manipulating external representations in problem-solving (Bocanegra et al. 2019). Action-perception loops operate quickly, triggered by the direct perception of an action affordance in the environment, and are not mediated by slower deliberative thinking. The resulting environmental changes may also facilitate more contemplative reflections, engaging different types of cognitive processes.
6. **Executive Functions.** If creative problem-solving is a process driven by actions in the world, then we must conceive of executive function (e.g., the allocation of attentional resources) and executive control (e.g., what information from long-term memory to retrieve) as systemic processes (Vallée-Tourangeau et al. 2015; Vallée-Tourangeau and Vallée-Tourangeau [Under Review](#)). The endogenous homuncular challenge of central executive functions in traditional models of working memory is reformulated by acknowledging distributed exogenous factors that come about through changes in the world; these changes guide and constrain the allocation of attention and the retrieval of long-term memory knowledge.
7. **Gesturing Expands Thinking.** Gesturing lightens the load on the speech-based memory store, by shifting some of the representational burden on a visuospatial store (Goldin-Meadow and Wagner 2005). The linear constraints of a speech-based representational system do not characterize how information can be conveyed in gesturing. Gestures can also enhance creative problem-solving by exploring the praxic potential of objects, unveiling additional action affordances (Kirk and Lewis 2017).
8. **Embodiment.** From a general interactionist perspective, the body can be seen as a semiotic medium and modality through which understanding is distilled and communicated. Body positioning and movements are used by teachers and learners to communicate and understand concepts or varying complexity (Alač and Hutchins 2004; Azevedo and Mann 2018). To adapt Hall and Nemirovsky (2012, p.

208), bodies don't simply serve "to carry around a mind that processed mental content." Rather sense-making is more productively understood in terms of interacting embodied agents (Steffensen 2017).

Enacting the Possible

Creative problem-solving in the world encourages us to appreciate the co-constitutive forces that synchronously and recursively shape the problem-solver and the environment in which he or she is embedded. Interactivity continuously reifies a shifting topography of action affordances. As a result, the possible is woven dynamically through movement and exploration. Creative problem-solving of the first-order kind reveals as well as creates the protean nature of the possible. The possible is thus best appreciated in terms of a transactional logic.

The genesis of a new idea is likely shaped by a complex configuration of processes involving a great deal of interactivity among people and things. Psychological research has hitherto been constrained by a dual commitment to methodological individualism and neurocentrism (Vallée-Tourangeau and Vallée-Tourangeau 2014b). From this perspective, a new idea arises in a person's head, and the cranial events that bring this idea about can be quantified and imaged. Neuroscientific measuring instruments work mostly with immobilized participants, and so they reduce the problem-solving activity to one that depends exclusively upon internal resources – such as those implicated in the solution of a remote associate problem illustrated earlier.

However, the radical scaling down of the processes responsible for the genesis of new ideas necessitated by these theoretical and methodological commitments decreases the likelihood that these research efforts can offer an explanation of creative breakthroughs in science, the arts, or indeed any other cognitive activity that has a physical component. Case studies of innovation and discovery track much longer temporal trajectories than those explored under laboratory conditions and involve a degree of interaction with

artifacts and people that are rich and complex. Findings such as the relative hemispheric asymmetry in insightful solutions to remote associate problems do not meaningfully inform how new ideas are formulated and developed in science (e.g., Darwin's efforts to formulate the theory of evolution in successively clearer forms through 1837–1838) or the arts (e.g., Picasso's intense period of preparatory work leading to *Les Femmes d'Alger*). A reasoner may toil for days or months (or even years) on an engineering problem or a work of art. This is not to say that scientists, scholars, or artists cannot be profiled along psychometric dimensions (such as working memory capacity or thinking dispositions), but a creative arc can be complex, interactive, and contingent. The lean theoretical offerings from the current debate in the psychology of insight are sharply exposed when discovery is seen as a protracted process that concatenates hunches, observations, and actions over time and space.

Systemic Thinking Model (SysTM). A shift away from methodological individualism calls for a reconceptualization of human information processing. The shift must allow for, rather than dismiss, the constitutive elements of first-order problem-solving. It must guide the study of the transactional processes coupling people and artifacts in the enactment of insight. The systemic thinking model (SysTM; Vallée-Tourangeau et al. 2015; Vallée-Tourangeau and Vallée-Tourangeau 2017) aims to address this gap. SysTM conceives thinking as a cognitive process that evolves in time and space and results in a new cognitive outcome. As such, it provides a conceptual framework to account for the emergence of new "cognitive possibles," surpassing what was likely or achievable, through the situated use of higher cognitive operations ranging from making inferences to problem-solving and decision-making.

The model distinguishes between deductive and inductive cognitive processing and posits that behavior can be induced from possible actions offered by the immediate environment as much as it can be deduced from mental processing. Second-order problem-solving has been exclusively modelled through deductive

processing where reasoners are constrained to rely on a mental representation of a problem space (Newell 1980). First-order problem-solving, however, is not well modelled by deductive processing proceeding from a representation of the problem space and its mental exploration. To account for the emergence of solutions in a situated agent-environment ecosystem, we need to extend our conception of cognitive activity to encompass not only deductive but also inductive processing. Inductive processing takes place in situations where it is possible to act upon, and interact with, the elements of a problem space. Such interactive situations support the perception of possible micro-actions within one's environment or "micro-affordances" (Ellis and Tucker 2000) that can be acted upon without being mediated by goal-oriented symbolic activity. Three-dimensional artifacts can be picked up, moved, rotated in physical space, and rearranged in the world. When agents engage in these exploratory actions, they transform their perceptual input while preserving their cognitive resources. This inductive processing paves the way to insightful but unpremeditated and serendipitous "aha" moments. Altogether, SysTM provides a framework to support the study and develop our understanding of how cognitive events may arise from the coordination of mental and physical resources underpinning insightful problem-solving.

Much remains to be understood, however, in relation to the impact of micro-affordances on inductive processing and the mechanisms that underpin first-order creative cognition. Evidence suggests that increasing interactivity and opportunities for inductive processing improves solution rates in insight problem solving (e.g., Fioratou and Cowley 2009; Henok et al. 2018; Vallée-Tourangeau et al. 2016; Weller et al. 2011), but also in complex probabilistic inference tasks: through the use of systematic video-based behavioral analyses, Vallée-Tourangeau et al. (2015, Experiment 4) demonstrated that reasoners who engaged in the most transformative actions were also more likely to make a correct Bayesian inference. Still, much remains to be understood about how this improvement is realized. Micro-affordances are largely studied in the context of motor-controlled actions (e.g., grasping), but little

is known about how, when, and for whom they may support insight in particular and cognitive performance more generally. More research is needed to identify how insight emanates from transactions between individual cognitive resources and environmental affordance properties along the spatiotemporal trajectory of thought.

Expanding the Realm of the Possible Through Insight: Methodological Reflections

Research efforts have offered interesting answers concerning the neural underpinnings of insight phenomenology, the role of a conceptual impasse as a triggering condition for unconscious representational restructuring processes, and the importance of cognitive capacities in the ability to solve so-called insight problems. These developments pertinently address what we have called second-order problem-solving. We contend, however, that creative cognition which the concept of insight might more meaningfully capture is a first-order problem-solving *activity*. To better understand how people *make* the impossible possible, research should forefront interactivity and casts insight as a relational phenomenon. Methodologically this means designing problem-solving tasks that allow participants to build and interact with physical models of the problem or the problem solution. Detailed qualitative coding of actions (e.g., Steffensen et al. 2016) and changes to the physical configuration of the problem can help better understand how the eight features of first-order problem-solving outlined earlier contribute to the discovery of a new idea that results in the solution to a problem. Designing interactive problem-solving task environments is the best way to escape the Procrustean trap of methodological individualism. To cast insight as a relational phenomenon also encourages observing groups of reasoners as they labor to develop new ideas and solve problems (Fiore and Wiltshire 2016). Steffensen (2017) offers an interesting example of problem-solving in the wild, and how insight is distilled through the language and actions of two interacting protagonists. Foregrounding interactivity thus also means

investing research capital in observing how insight emerges in dyadic collaborative problem-solving activity. The importance of the deep connection between people and the rich world within which they are situated for understanding insight also has implications for researchers of the possible more generally: in all likelihood, and perhaps paradoxically, what people find conceivable, imaginable, or thinkable might be better understood at the point of contact between the mind, the hands, and the world. The possible is not just an intellectual concept; future research on the possible would benefit from expanding its scope to include the study of perceived affordances that is the role played by the perception *possible* actions played in what people deem possible.

Conclusion

We opened this entry with some reflections on the etymology of the word “insight,” noting the tension between “inner” and “sight” and the relation with “new possibles.” When research focuses on the narrow neuro-temporal signature of insight in second-order problem-solving, it seems appropriate to characterize insight as a mental phenomenon, as an inner state of mind. However, when creative problem-solving is assessed from an interactivist perspective, the origins of the new possible seem to be in the world, that is based on the perception of changes in the world. Creative problem-solving is synonymous with changes in the world – changes to a sketch, a manuscript, a sculpture, and a prototype. These changes may reflect the implementation of a plan, but they may also be brought about or brought through actions that were not premeditated; the changes may also be entirely serendipitous in nature. A hyphen might be more appropriate in this instance, “in”-“sight” rather than “insight,” to better capture this perceptual dimension of creative problem-solving and underscore the importance of enacting and tracking changes in the world in the genesis of new ideas. We recently conjectured (Vallée-Tourangeau and March 2019) that new ideas are perceived rather than cogitated, and in that case, creativity and the genesis of new possibles might be better captured with the term “outsight.”

Abstract

Inspiration denotes a mundane experience that has a long history of being reflected upon and aspired to. However, due to its complexity and mystical associations, it has received until now little scientific attention. When studied

empirically, this phenomenon is typically understood as a cognitive or motivational process, one that involves both a receptive (inspired by) and agentic (inspired to) dimension. Its relation to creativity in particular has been of considerable interest, with different authors portraying inspiration as either an antecedent or consequence of getting creative ideas. Sociocultural psychology, for example, understands inspiration as a state of active receptivity, one in which the person is animated to pursue and explore the possible. This entry starts with the definition of inspiration and its history, before moving on to summarizing empirical research in this area. It focuses in particular on the relation between inspiration, creativity, and the possible within a sociocultural framework. Some reflections on how to cultivate inspiration or, rather, the conditions that foster it, are offered towards the end.

Keywords

Inspiration · Inspired by · Inspired to · Creativity · Possible · Sociocultural psychology

While the notion of inspiration commonly appears in lay discussions, scientific studies of this phenomenon are scarce. On the one hand, lay people are reminded of Edison's remark that genius is 1% inspiration and 99% perspiration or, conversely, of the ancient view that creators and leaders work with the help of "divine" inspiration. Scientific research in this area, on the other hand, has a great contribution to make both to our understanding of inspiration and of the possible, by pointing to the mind's readiness to expand its own range of possibilities. This kind of research is of interest across disciplines and, indeed, inspiration attracted attention in a number of fields, e.g., theology, literary criticism, management, engineering, education, the arts, as well as several branches of psychology (Thrash et al. 2014, p. 495).

Denoting a familiar type of experience, inspiration is a multifaceted phenomenon that can be triggered by a variety of encounters: with role models and mentors, with nature or beauty, or with the divine in revelation (Thrash and Elliot 2003, p. 871). Moreover, inspiration can be experienced

at different levels of "intensity," from more mundane forms of getting new insights to intense moments of epiphany and awe that can mark one's very existence (see entry ► "Awe"). It is specific for the activity of talented artists, scientists, inventors, or entrepreneurs, but also present in daily events and undertakings. As Hart (1998, p. 10) noted, "what is common among these is the idea of inspiration as a specific and nonordinary process of learning or knowing." Inspiration is thus an experience that involves not only affect but also cognition, motivation, and, more generally, the person as a whole in his or her interaction with the world.

This entry will start by defining inspiration and considering it in historical context. It will continue with a brief review of empirical research on inspiration – both quantitative and qualitative – and focus on a sociocultural approach to it. Last but not least, it will consider how inspiration can be cultivated, even if it should not and, indeed, cannot be willed.

Definition and History

Etymologically, the notion of inspiration comes from the Latin *inspirare* which means "to breathe into" (*in* plus *spirare* or "to breathe," also related for the word for "spirit"), "to be filled," or "to inflame." Related to the Latin conception is also the Greek origin of the term for *enthusiasm*, which implies being possessed by a god or becoming the recipient of divine inspiration (Hart 1998, p. 8). Each of these associations continued through the ages, e.g., the view that inspiration comes from above or from beyond the person, that it somehow takes possession of the creator, and that it generates strong emotional reactions. These ideas resonate with the general definition listed in the Oxford English Dictionary: "a breathing in or infusion of some idea, purpose, etc., into the mind; the suggestion, awakening, or creation of some feeling or impulse, especially of an exalted kind" (Simpson and Weiner 1989, p. 1036).

Several of the features mentioned above – e.g., ideation and insight, creativity, exaltation – are present also in scientific definitions and approaches. For example, Hart noted that:

Inspiration is a specific epistemic process (...) characterized by a remembrance or recognition of some knowledge or perspective valuable in the social or psychological context given. The acquisition or awareness of knowledge takes the form of an expansion of understanding that involves (...) transcendence of the conventional. As such, inspiration describes (...) knowing that can be cultivated but not willed. (Hart 1998, p. 32)

This definition captures, to some extent, what Thrash and Elliot (2003) identified as the three main components of inspiration: transcendence (awareness of new possibilities), evocation or receptivity (not attributing the responsibility for being inspired to oneself), and motivational approach (positive activation). The main difference lays in the cognitive or knowledge emphasis of the former, and the motivational emphasis of the latter. Both conceptualizations, however, underline the distinction between a more passive and receptive element of inspiration (“being inspired by”) and a more dynamic, action-oriented one (“being inspired to”) (for a more detailed discussion see Thrash and Elliot 2004). Last but not least, the definitions above both point to the link between inspiration and creativity or creative ideation (see entry ► “Creativity”).

These associations have, of course, their own history, and it is interesting to note that the meaning, place, and value of inspiration varied across historical times (see also Hart 1998). For example, in the ancient world, inspiration was considered to come from outside the person, from gods or the muses, who would “fill up” their recipient with skills and ideas. Interestingly, two opposing views of this experience were already available: the rational and solar path of Apollo versus the wild, unpredictable, and orgiastic influences of Dionysus. The belief in divine inspiration was kept through the Middle Ages, resonating with the value placed, at the time, on faith and revelation. The Renaissance marked a turning point in this regard, gradually leading to the “internalization” of inspiration and its processes; i.e., inspiration was attributed to the unique qualities of those inspired. The advent of psychology as a science, many centuries later, took further steps into making inspiration and intra-psychic phenomenon, replacing it with

illumination or insight and attributing it to the unconscious. This last association, cemented during Romanticism, helped it gain in popularity, but also made it difficult to advance the scientific study of inspiration, at least within the positivist tradition. In contrast, contemporary accounts of creative people tend to attribute inspiration back to the environment, contract with nature, and even transcendental influences (Thrash and Elliot 2003, p. 872).

What this brief historical overview points us to is the fact that, beneath the surface of tidy definitions, inspiration as a phenomenon presents us with a range of paradoxes. They are represented by the simultaneity, in the experience of being inspired, of different, oftentimes contradictory, states or impulses: passive and active, order and chaos, rationality and irrationality, equilibrium and disequilibrium, individuation and de-individuation, conscious and unconscious, external and internal, divine and human, ordinary and extraordinary, among others. This state of affairs made Thrash and colleagues note that “it is through grappling with the paradox of inspiration, we argue, that psychology will shed light on the farther reaches of human nature” (Thrash et al. 2014, p. 496). And, we can add here, also help us reach a deeper understanding of creativity and what it means to explore the possible.

Research on Inspiration

As mentioned from the start, empirical research on inspiration has been scarce, even if not altogether absent. Progress in this area has been hampered, as Thrash et al. (2014, p. 495) remarked, by “definitional ambiguities and inconsistencies, an absence of foundational construct validation research (...) and a variety of myths and misconceptions about inspiration that have arisen from sources other than rigorous science.” And yet, the past three decades have witnessed an increased number of studies in this area, both quantitative (psychometric and experimental) and qualitative (observation and interview-based).

Many of these advances can be attributed to work done by Todd Thrash and Andrew Elliot. As mentioned in the previous section, they proposed

an influential three component framework of inspiration including “motivation (e.g., activation, energy), evocation (e.g., feeling overtaken, uncontrol, attraction from the object, openness), and transcendence (e.g., positivity, enhancement, clarity)” (Thrash and Elliot 2003, p. 873). Later on, a process model was added, one that distinguishes being *inspired by* and being *inspired to*. In linking the two models, the authors proposed that being inspired by gives rise to transcendence and evocation, while being inspired to gives rise to approach motivation (Thrash and Elliot 2004). The study of these components and processes required a valid measurement tool and this was conceived by Thrash and Elliot (2003) in the form of the Inspiration Scale (IS), an eight items, self-report instrument designed to capture primarily trait inspiration (although claimed to be useful also for the study of state inspiration). The IS comprises two subscales with four items each, one focused on frequency and the other one on intensity. Examples of items include: “Something I encounter or experience inspires me” and “I am inspired to do something.” While these formulations sound rather general, the IS has proven, according to its authors, good psychometric properties, demonstrating both invariance across time and invariance across populations.

Using this scale, Thrash and Elliot (2003, p. 885) documented a number of correlations between inspiration and a series of psychological and biological indicators. For instance, inspiration was found to correlate positively with the behavioral activation system (but not the behavioral inhibition system), with extraversion and openness to experience (but not with neuroticism and conscientiousness; see entry ► “[Openness to Experience](#)”), with positive emotions (but not negative ones), with work mastery (but negatively with competitiveness), with intrinsic motivation (but negatively with extrinsic motivation), with creativity, perceived competence, self-esteem, and optimism. These findings have been discussed by the two authors in relation to the three components of inspiration and considered to support the general model. However, a distinctive limitation of these studies has to do with their correlational nature, making it difficult to draw

causal inferences. Thus, for example, one might wonder if creativity, perceived competence, self-esteem, and optimism are antecedents, consequences of inspiration or both.

There are few experimental investigations of inspiration, principally emerging from the work of Takeshi Okada and his collaborators, who focused primarily on the relationship between inspiration and creativity. For example, they tested recently whether viewing or copying prior examples impacts creative outputs in art (see Okada and Ishibashi 2016). In three experiments, they found evidence that copying unfamiliar abstract drawings led participants to produce drawings what were qualitatively different than the original model, that exposure to unfamiliar styles facilitated creativity in drawing, and that both copying and viewing artwork with an unfamiliar style had this effect (while merely thinking about alternative styles did not). The authors explained these findings by pointing to the relaxation of cognitive constraints and the emergence of new perspectives (see entry ► “[Perspective](#)”). When people imitate the works of others, they relate them to their own cognitive framework but, when the latter does not connect, the framework itself needs to be challenged (i.e., constraint relaxation takes place) and changed (through the birth of new perspectives). These are important findings, but they need both to be replicated, including on different populations, and complemented by a richer description of inspiration as a process, an aim accomplished best by qualitative research.

Hart (1998) reported one of the first investigations of this kind, using 70 in-depth interviews with participants from a wide range of professions (unlike psychometric and experimental studies, mostly conducted on undergraduate students), to examine what experiences and meanings are associated with inspiration. He discovered four phenomenological characteristics of inspiration: connectedness, openness, clarity, and energy. While one or the other might get to dominate a person’s experience of inspiration, the phenomenon itself requires all four dimensions. Another, more recent study, was conducted by Glăveanu and colleagues (2013) on the experience of creators working in five different domains: art, science,

design, music, and film scriptwriting. While this research was not primarily focused on inspiration, it did document, in creators' discourses, the paramount importance of this phenomenon. For instance, in referring to their approach to work, artists often defined themselves as "sponges," as being "90% in a receptive state," and allowing themselves to be "impregnated" by things and people who enter an inner "factory of fermentation." In design "inspiration comes from everywhere," so you need to "keep your antennas out," to be "attentive" and "open to the world," to be "nurtured" by the work of others, to "collect" things, and to store them in a "bank" of ideas. Scriptwriters have habitually the attitude of a "hunter in the forest," "permanently nourished by the spectacle of others," and so on. These accounts, as we shall see next, are important for reexamining the link between creativity and inspiration and, even more, for reflecting on its relation to the possible.

Inspiration, Creativity and the Possible

One of the most extensively studied connections in the literature is that between inspiration and creativity. In fact, this relationship is so close that Thrash and colleagues (2014, p. 496) listed various possible roles played by inspiration in the creative process including delivering ideas, evoking creative states, facilitating insight, making creators aware of ideas, motivating them, and even being synonymous with insight or with creativity itself. While inspiration might participate in more than one way within the creative process, it is counterproductive to equate the two. The latter would make it difficult to capture the unique characteristics of each or, more generally, to consider the temporal order between these phenomena.

With regard to temporality, one common belief is that inspiration *precedes* creativity. In other words, one needs to feel inspired before producing something novel and valuable. This is what Hart (1998) associated with the phase of waiting for inspiration or illumination in the creative process. He wrote that, "the extent to which we courageously invest or risk our energies in a particular

venture will reflect in the depth of the encounter and of the quality of the inspiration" (p. 8). One of the main limitations of this standpoint is that inspiration tends to be reduced to the first, initial or preparatory stages of creativity – couldn't a creator feel inspired throughout? Thrash and his collaborators seem to believe so. In fact, they proposed and tested a rather usual idea: that inspiration to create is "a motivational state that is evoked in response to getting a creative idea and that compels the individual to transform the creative idea into a creative product" (Thrash et al. 2010, p. 470). As such, instead of fueling creative ideation, inspiration is rather *fueled by it*. The emerging image is one of inspiration as mediating the link between the creative idea and its realization. As mentioned by Thrash et al. (2014, p. 501), "all forms of inspiration are fundamentally constructive processes in which new entities (e.g., poems, future selves, or a spiritual life) are brought into fruition."

How does this claim fare when it comes to empirical testing? Thrash and colleagues (2010) offered some evidence supporting their view, at least in the field of creative writing. Several studies in this area evidenced the fact that getting creative ideas and being inspired are distinct phases and that the former precedes the latter. Moreover, inspiration predicts creativity in writing (while effort predicts technical merit). Last but not least, peaks in inspiration predict peaks in creativity. Based on this, the authors proposed the "transmission function" of inspiration, mediating between the creativity of the idea and that of the product. They concluded as follows:

Although creativity researchers sometimes portray inspiration as an account of the *origin* of creative ideas – creative ideas are given by God or a Muse – our portrayal of inspiration as concerning the *transmission* of creative ideas is consistent with its usage in theology. Rather than being a source of creative ideas, inspiration is the resulting intentional (i.e., object-focused) state, which has the creative idea as its content and actualization of the idea as its aim. (p. 470)

But, once more, if inspiration is not the source of creative ideas, can it be reduced to a mere "response" to them? More importantly, is being inspired a state of mind that is closed to the

possible – in this case, possible new ideas emerging – and focused on the realization of one single, inspiring idea? A sociocultural reading of inspiration differs considerably in this regard: it views inspiration as opening up the possible rather than turning one possibility into actuality. As a discipline focused on the interdependence between mind and culture (Shweder 1990), sociocultural psychology considers inspiration to be both a relational process, connecting person and environment (both “internal” and “external”), and a personal experience. The essential characteristic of inspiration as an experience rests in the mind’s readiness to be inspired. As Pasteur allegedly remarked, fortune favors the prepared mind (Eckert and Stacey 1998). This means that while specific encounters, ideas, or events might have a higher chance of inspiring people (to act or, more specifically, to act creatively), inspiration itself requires the “collaboration” between person and environment in which the person experiences a state of *alert receptivity*. This state of mind captures one of the main paradoxes of inspiration as a phenomenon: the interplay and, to a great extent, simultaneity between passivity and activity, between being inspired by and being inspired to. What is the person alert and receptive to? In summary, he or she is *receptive to new, emerging perspective, and alert as to what their possibilities might be for both thought and action*.

There is, thus, an important connection to be made between inspiration and the possible. Previously, Glăveanu (2017) distinguished between three inter-related, cyclical stages in engaging with the possible: awareness, excitement, exploration. Inspiration characterizes best the experience of excitement about the possible and what might come next, a basic form of receptivity and openness. As such, the experience of being inspired is often triggered by a new perspective that makes the person aware that more is conceivable within a given situation. This understanding does not subordinate inspiration to creativity – indeed, someone might be inspired to do other things, for instance, meditate rather than create, and there are moments in the creative process that are seemingly void of inspiration (i.e., when new perspectives are neither

encouraged or looked for). There are here some points of overlap with Thrash’s conception and also some major differences. The main difference has to do with the fact that inspiration is not seen as a search for how to best implement a certain idea, but a search for new perspectives that open up new possibilities. In addition, a new dimension that is added by the sociocultural approach is the community one. Psychological accounts typically locate inspiration within the person or, at best, interpersonal exchanges. Yet, inspiration is also a social and cultural phenomenon inasmuch as broader historical trends, making up the *zeitgeist* of a certain era and place, influence what fuels the imagination and creativity of an individual or a community.

Cultivating Inspiration

A main point of agreement among different theorists is that being inspired is associated with (mainly) positive consequences. Key among them, as argued here, is the person’s propensity to engage with what is possible and explore possibilities beyond the initial source of inspiration. As such, a last important question emerges: how can one cultivate inspiration?

Before addressing this question, we would need to reflect first on how inspiration is expressed since, not knowing what to look for, one would hardly be able to distinguish between being inspired and simply being active or interested. In line with the sociocultural account sketched in the previous section, a person is inspired when he or she explores existing ideas and perspective with a view towards what could emerge from them. Essential to note, once a certain perspective is embraced and pursued, one can no longer talk about inspiration but continued interest. Inspiration, as described before, is characterized precisely by an active and receptive openness to the possible; once a commitment is made, inspiration morphs into other forms of motivation (e.g., the develop further, to translate a perspective into practice). At a phenomenological level, therefore, inspiration is often experienced as an insight that is *about to*

come, that is driven by the source of inspiration (not by the person; what Thrash and colleagues referred to as evocation), that is on the “tip of the tongue.”

What are possible sources of inspiration then? As Hart (1998, p. 27) aptly wrote, “given the right mindset, virtually anything could be found to be a trigger.” While creators working in various domains might mention that they find new, interesting perspectives in nature, in dialogue with other people, by exploring their own unconscious, by copying the work of others, etc. (see Glăveanu et al. 2013; Eckert and Stacey 1998; Okada and Ishibashi 2016), in reality the role and impact of each one will depend on existing dialogues and perspectives. In some cases, the value of what seems like sensible advice, for instance, to look for conceptual distant rather than proximal sources of inspiration, is disproven by research (Chan et al. 2015). As such, producing lists of what could help people get inspired is a rather futile exercise; what matters more is cultivating the kind of receptivity to one’s environment that invites moments of inspiration. In this regard, Hart’s (1998) advice is to reflect on one’s focus, on trust, letting go, and listening. These are useful pieces of advice as they invite us not to commit too soon to one solution, idea, or perspective, to let things incubate for a while, to learn to let go of old, conventional ideas and, last but not least, to listen actively and openly to others and to oneself. Instead of formulating a “one method fit all” approach, cultivating inspiration would benefit from developing meta-cognitive skills that allow the person to monitor when, where, and how he or she gets inspired. Keeping track of the process, including surrounding oneself with potential inspiration triggers, requires considerable reflexivity.

Most importantly, one needs to remember that while inspiration can be cultivated, mainly by developing a deeper understanding of its individual dynamic, it can never be willed or forced. Just like being inspired by the sense of new possibilities is an integral part of our lives, being able to grasp these possibilities requires patience and letting go, not only active pursuit. As Thrash et al. (2014) eloquently remind us:

Yes, it is indeed difficult to elicit inspiration. Inspiration tends to happen to people spontaneously in the natural context of everyday life. Authentic inspiration experiences usually are not the result of a deliberate effort of one party (e.g., a researcher, employer, or author of a self-help book) to inspire another; literally and figuratively, inspiration refers to ‘breathing in,’ not to being ‘blown into.’ (p. 506)

Conclusion

Inspiration is an ordinary experience which has an important part to play both in creativity and in how we engage with and explore the possible. While it has been theorized in the past in purely psychological terms, as a motivational state or an epistemic process, inspiration actually takes place at and through the encounter between person and world. Indeed, society, culture, and community all participate in getting inspired, even if their work is often invisible. As such, a sociocultural reading of this phenomenon describes it as active receptivity, a socio-psychological and embodied state in which a sense of excitement about what is possible is both triggered and maintained. This means that inspiration might not start from a creative idea and lead to its realization, as it has been proposed in the past, but precede this stage. In fact, choosing to pursue a particular idea might very well signal the end of being inspired. In contrast, inspiration, as discussed here, is characterized by the open-ended process of looking for new perspectives based on the relationships established between them. As such, it can be cultivated by becoming sensitive to new perspectives acquired through dialogues with others, exploring nature, reflecting on one’s own experiences, valuing accidents and the unexpected, etc. In the end, while inspiration itself can never be willed, the conditions for being inspired can and should be understood and fostered; after all, this is a state reached most easily by *prepared minds*.

Intelligence

Robert J. Sternberg

Department of Human Development, College of Human Ecology, Cornell University, Ithaca, NY, USA

Abstract

This chapter reviews conceptions of intelligence. It starts off with the conception of Albert Binet. Binet truly understood intelligence. But many of his insights were later lost. The chapter discusses the following: first, the psychometric conception, pointing out that, in some ways, the psychometric conception of intelligence has closed off rather than opened up possibilities for the future; second, cultural conceptions of intelligence, which seek to open more possibilities for the future; and third, the conception of adaptive intelligence, which views intelligence in terms of real-world demands rather than demands artificially imposed by contrived general-intelligence tests. Finally, the chapter draws conclusions.

Keywords

Adaptive intelligence · Alfred Binet · Cultural approach · Intelligence · Psychometric approach

The concept of intelligence once promised to open up a world of possibilities. What scholars and practitioners at the time did not realize at the time was that, for many people, it would close worlds of possibilities. What started off as a positive vision thus became a much more mixed one.

The Contribution of Alfred Binet

The positive vision started with the work of Alfred Binet and Theodore Simon at the turn of the twentieth century in France (Binet and Simon 1916). Binet and Simon had been asked to develop a test of mental abilities that would

distinguish those who could profit from normal schooling from those who could not – who needed special classes where the pace of learning was slower and where special remediation was offered to help children realize what appeared to be their limited potential. Binet and Simon's work led to the development of scales to measure levels of intelligence. There were some critical ideas underlying Binet's work, here and elsewhere.

First, intelligence is judgment. It involves a critical faculty and especially self-criticism. Most of all, it is used in order to adapt to the environment – the real environment in which we live.

Second, intelligence is potentially modifiable. Binet planned to introduce mental orthopedics to help children improve their intelligence. He died before he got around to developing the idea fully.

Third, intelligence tests can be designed to offer opportunities, not to take them away. His test was designed to offer to children who were slow-learners opportunities to learn in classrooms designed especially for them. And the test was further designed to ensure that children who were normal learners but behaviorally challenged and challenging would not be shunted to special classrooms for slow learners because teachers in regular classrooms did not want to deal with them.

The Traditional Psychometric Approach to Intelligence

Many of these assertions were not things one could take for granted in the day of Binet. Sir Francis Galton, a British polymath, had different ideas about intelligence (Galton 1869/1892/1962, 1883/1907/1973). Galton's beliefs came close to being the opposite of Binet's. Galton believed that intelligence inhered in psychophysical abilities, such as pitch discrimination and visual discrimination, rather than in judgment. Further, he believed that intelligence was largely fixed rather than modifiable. Third, he viewed intelligence as something that did and should deprive certain

people of opportunities, even reproductive ones, as he was a eugenicist. So, Binet was entering into a domain where the beliefs he introduced were by no means ones that could be taken for granted. Binet was largely about opening up possibilities, while Galton, in many ways, was about closing them off. Who won, so to speak? Oddly, each got a little of his way, but for different reasons.

About the same time that Binet was doing his work on developing an intelligence test, Charles Spearman (1904, 1927), a British scholar, was studying intelligence, but from a different vantage point. He was more theoretical and less applied in his orientation than Binet. His fundamental insight – although he had many other insights as well – was that various tests of intelligence, when correlated with each other, all correlated positively. Spearman invented a statistical method, which he called “factor analysis,” which would provide a way of finding hypothesized latent sources of individual differences that underlay mental-ability test scores. When applied to various tests, factor analysis yielded a single general factor – a factor common to all of the mental-ability tests – as well as factors or sources of individual differences specific to each of the tests. The theory thus came to be called the “two-factor theory,” because it hypothesized two kinds of factors – general and specific – underlying intelligence. As one might expect, Spearman was much more interested in the general factor, as it permeated all of the tests. He did not know just what the general factor represented, but he suggested it represented what he referred to as “mental energy.”

Many different factor-based, or “psychometric,” theories emerged from the work of Spearman. For example, Godfrey Thomson (1916), a Scottish psychologist, suggested that the fact that there was a general factor of intelligence did not actually suggest that a single capacity underlay performance on intelligence tests. Rather, it suggested that one or more things may underlay performance on all of the tests. If, say, 20 mental capacities were required for performance on all of the mental-ability tests, then they all would appear in the general factor. The general factor suggested only that there were some common mental

capacities of an unknown number. Thomson called these capacities “bonds.”

Louis Thurstone (1938) later suggested that Spearman and Thomson both were wrong, that in fact what underlay intelligence were seven related but distinct “primary mental abilities,” namely, verbal comprehension, verbal fluency, spatial visualization, inductive reasoning, memory, numerical skill, and perceptual speed. Others pointed out that because Thurstone’s factors were correlated with each other, these factors could themselves be factored to yield a general factor, so that the argument became one of which was primary, general intelligence or the Thurstonian primary mental abilities.

Arguments such as these persisted until John B. Carroll (1993) factor-analyzed practically all of existing data sets with factorial analyses of intellectual abilities and proposed what he called a “three-tier” model of intelligence. His model, although not the first hierarchical one, synthesized the theories and findings of many who came before him. The first tier consisted of quite specific factors, the second of group factors more akin to Thurstone’s, and the third only of *g*. This model, and variants of it, one called CHC (Cattell-Horn-Carroll) theory (McGrew 2005), dominates psychometric thinking about intelligence today.

From the standpoint of an Encyclopedia of the Possible, I would argue that the development of mainstream psychometric theory on intelligence has been disappointing. There are three reasons for this.

First, the tests that resulted from the psychometric approach have been at least as much about closing off possibilities as about opening them up. Psychometricians have tended to believe that intelligence is relatively narrow, fixed, and largely genetic in origin. Moreover, testing of intelligence and related skills has been used as much to close off possibilities as to open them up. Who will be admitted to a selective university? Who will be admitted to a gifted program? Who will be selected for financial aid? Who will be hired for a job and who will not be? Who will be placed in higher school tracks and who in lower ones? In more extreme cases, who should be allowed to enter a

country and who should not? Who should be allowed to have children and who should not? Which socially defined races, nationalities, or ethnic groups have more intelligence, and which have less? The field of intelligence became one of closing off rather than of opening up possibilities (see Gould 1981; Sternberg 2019a, 2020c, d, 2021). Put another way, Binet won over Galton on the content of intelligence tests but lost on everything else.

Cultural Approaches to Intelligence

Investigators in some traditions other than the psychometric one have tried to be broader and more inclusive in their conceptualization of intelligence. For example, cultural approaches have viewed what is adaptive as in large part as culturally determined (see Sternberg 2020b). Skills that are valuable and that are valued in one culture may be of much lesser value or of no value in a different culture. For example, ice fishing or hunting skills are extremely important for adaptation in some Northern environments, such as in rural parts of Alaska, but may have no adaptive significance in many other environments (Grigorenko et al. 2004). Even what is considered to be intelligent may differ from one cultural milieu to the next. Most informal or folk theories of intelligence are much broader than expert conceptions of intelligence based on psychometric testing (Sternberg 2004). These cultural conceptions represent a broader array of possibilities in life and in conceptions of intelligence than are represented in traditional theories of intelligence.

The cultural theories have been a step forward, but in a sense, they have posed some problems that are the opposite of the ones posed by the psychometric theories. In particular, they have sometimes left people feeling that there is no common core at all to intelligence. They generally have not yielded measurements that are psychometrically sound or generalizable in any way beyond a narrow swatch of people. And they have failed to gather the large following that psychometricians have gathered with the ready application of their intelligence tests to large numbers of people. Often, it has seemed more important to

quantify than to ensure that the quantification is valid in any broad sense (beyond criteria chosen by the same culturally homogeneous people who created and scored the tests). Are there any other options?

I believe we need to return to the original definition of intelligence proposed by Binet and Simon (1916), Wechsler (1940, 1944), early intelligence theorists (“Intelligence and Its Measurement” 1921), and later intelligence theorists (Sternberg and Detterman 1986) regarding intelligence as an adaptation to the environment. I believe that, somehow, in the rush to measure intelligence and related skills, the original definition as well as the conception of Binet somehow got lost. Scholars and technicians became so concerned with the preservation of the intelligence-testing tradition that they began validating new tests against the old ones. This meant that a test was good if it measured what the older tests measured. That closes off all possibility that the conception of intelligence could be broadened because a test would be viewed as valid only to the extent it measured what tests of the past measured. We can do better than that. What would it mean to open ourselves up to a broader conceptualization of intelligence as adaptation to the environment, rather than merely one of intelligence as whatever it is that intelligence tests happen to test (Boring 1923)?

Adaptive Intelligence

Another approach to intelligence is to look at it in terms of its original purpose, namely, broad adaptation to the environment. What are the skills people need in order to fit into the environment or to make the environment work for them?

On this point of view – a more biologically oriented one – intelligence is about not only maximizing one’s own future possibilities, but also preserving future possibilities for others of one’s own species. If humans are to be “intelligent,” they cannot be destroying the environment for the generations to come (Sternberg 2019a). That is, what does it mean to be intelligent if people are working, purposefully or inadvertently, to

increase global climate change, pollution, and other degradations of the environment in which they live? Intelligence should be about creating possibilities for the future, not destroying them.

IQ tests do *not* measure adaptive intelligence. The problem is that real-world adaptive tasks and the kinds of abstract-thinking tasks that appear on conventional intelligence tests are very different from one another (Sternberg 2020e). Indeed, the characteristics of real-world tasks are almost *opposite* to those of IQ-test problems. That is not only why IQ tests fail to measure adaptive intelligence, but also why the whole set of theories of general intelligence has proven to be such a thin reed when it comes to understanding intelligence as adaptation. Real-world problems, unlike IQ-test problems, (a) are for high stakes, sometimes life-changing ones; (b) are emotionally arousing so that emotions often cloud people’s rational judgment; (c) are highly context driven, requiring that people balance many different and often conflicting interests; (d) are lacking in any single uniquely determined “correct” answer and are not susceptible to presentation in multiple-choice or short-answer format; (e) are lacking anyone even to inform us that there is a problem to be solved; (f) do not specify the nature of the problem, which often is unclear; (g) are typically in need of a collective solution by people with diverse backgrounds, points of view, and interests; (h) typically offer only vaguely defined paths to solution, or even more often, no seemingly good path at all; (i) often unfold and need to be solved and then sometimes resolved over long periods of time; (j) often leave it difficult to ascertain what particular information is needed to solve a problem and where that information is to be located; and (k) are often plagued by numerous items of false and often misleading information, sometimes inserted deliberately, and therefore poised to make a useful solution more difficult to obtain. Is it any wonder that people can excel in general intelligence yet be unable to solve basic adaptive problems in their lives?

Researchers in cognitive psychology have found that transfer of training – i.e., generalization of what one has learned from one setting to another – is hard to obtain, even when two tasks

are actually isomorphic, that is, structurally the same (Gick and Holyoak 1980, 1983). The more different two tasks are from each other – the more remote the connection – the less the transfer that is obtained. Adaptive-intelligence problems are wholly different from general-intelligence ones.

According to the theory of adaptive intelligence, there are four abilities central to adaptation to everyday environments and creating possibilities for the future.

Creative Abilities

Creative abilities are used to generate ideas that are both novel and somehow useful (Kaufman and Sternberg 2019). For example, a problem such as increasing global climate change requires creative solutions, which have not been rapid in coming forth. People who are creative tend to gravitate toward activities in which they can create, discover, explore, invent, imagine, and suppose.

Creative abilities involve both skills and attitudes. The skills are needed to generate the novel ideas, but the attitudes are needed to want to generate the ideas in the first place. That is, creative skills are largely useless if they are not actually deployed. Why would people not deploy their creative skills? A triangular theory of creativity (Sternberg 2018) suggests that deploying creative skills requires three interrelated attitudes that are often difficult to marshal.

The first attitude is defiance of oneself. To create new possibilities for the future, one sometimes has to let go of beliefs or ideologies one has accepted in the past. This is hard to do because it means admitting that one's prior beliefs were wrong or, at least, lacking in some respects. Many people do not want to admit to error.

The second attitude is defiance of the crowd (see also Sternberg and Lubart 1995). Defiance of the crowd requires the individual to think or act in ways contrary to the ways other people think or act. But there usually is social pressure to follow the crowd, ranging from others criticizing one's defiance to others ensuring that one is discharged from one's work, or worse, that one is imprisoned or killed. Yet, creativity requires one to follow a path different from that others have followed. Otherwise, one cannot have novel ideas.

The third attitude is defiance of the *Zeitgeist*, or worldview that prevails at a given time. A worldview is often preconscious. One is not even aware one has it. For example, ridding the United States of slavery in the mid-1800s would not seem today to be a challenging question of a worldview – why should anyone at all be enslaved? But at that time, many people in the country – all of them White – believed in slavery and saw it as a viable future for the country. A Civil War was fought over the issue.

It is troubling that future possibilities can be achieved only through creative envisioning of a new future, yet so-called “intelligence tests” do not measure creativity at all (Sternberg 1997). To the extent that intelligence requires not only reruns of what has been done before, but also the creation of new future possibilities, existing tests fall far short. The problem is that the people selected for a power structure that was not chosen for creativity also may not see their way to valuing or rewarding it.

Analytical Abilities

Analytical abilities are what existing tests of intelligence attempt to measure. The tests further measure the knowledge base on which those analytical abilities act (Sternberg 2020a). People who are analytical tend to gravitate toward activities in which they can analyze, evaluate, critique, judge, assess, and compare and contrast.

Intelligence tests, as noted earlier, primarily measure analytical abilities, as well as the knowledge based upon which they operate. The tests tend to measure analytical abilities for fairly abstract kinds of items, such as number series or word classifications, so that the results are as general as possible – that is, as relevant as possible to general intelligence, but this practice comes at a cost.

The question then can become one of how well tests of abstract analytical reasoning measure analytical reasoning (and other forms of reasoning) in more domain-specific contexts. It has been sought to answer this question in the context of scientific/technological/engineering/mathematical (STEM) reasoning. Tests of reasoning for STEM disciplines were devised. The tests required

participants to generate alternative scientific hypotheses, generate scientific experiments, and draw scientific conclusions (Sternberg and Sternberg 2017; Sternberg et al. 2017, 2019, 2020). Further scientific tests as well as tests of general intelligence were done. The tests of STEM reasoning correlated positively with each other, but they did not correlate as well (and sometimes even correlated negatively) with traditional ability tests, such as number series, letter sets, and SAT. So, conventional intelligence tests and college-admissions tests do not even necessarily measure particularly well those aspects of analytical reasoning relevant to STEM research. Put in another way, it is not clear just how generalizable the skills are that are measured by conventional tests of analytical aspects of intelligence.

Practical Abilities

Practical abilities, also referred to collectively as “common sense,” are used to put ideas into practice and to convince others of their value. People who are high in practical abilities are able at implementing ideas, putting ideas into practice, executing on ideas, and persuading others of the value of their ideas. We have found (Sternberg and Hedlund 2002) that (a) practical-intelligence tests tend to intercorrelate positive with each other; (b) sections of practical-intelligence tests – managing oneself, managing others, and managing tasks – tend to intercorrelate positively with each other; and (c) practical intelligence is distinct from IQ.

Why is practical intelligence distinct from general intelligence? The reason is simple: lack of transfer. People can be intellectually adept at solving abstract problems and fail to transfer their skills to everyday problems; conversely, people can be intellectually adept at solving everyday problems but fail at abstract ones.

Wisdom-Based Abilities

Wisdom is one’s ability to use one’s knowledge and other abilities to achieve a common good, by balancing one’s own, others’, and larger interests, over the long-term as well as the short-term, and through the infusion of positive ethical values (Sternberg 2019c). Wise people look out not

only for their own interests and the interests of their family, friends, and other people like them, but also for others who are unlike them. They seek to balance their own with others’ and larger interests. They recognize that, truly, a rising tide raises all boats.

Schools do not teach for wisdom. Indeed, an analysis of US textbooks from the early twentieth century to the present day reveals that, as time has gone on, teaching of wisdom-based content has decreased at the same time that teaching of strictly academic content has increased (Sternberg 2019b). It is little wonder that, at the same time that people’s IQs rose 30 points in the twentieth century (Flynn 1987, 2012), people’s wisdom seems, if anything, to have gone down. If one looks at the problems nations face around the world, including their enthusiastic penchant for voting in dictators or would-be dictators, it is clear that IQ has bought people little, nothing, or perhaps negative gain in terms of being able to solve in a coherent way the problems the world faces.

Conclusion

Intelligence has traditionally been viewed within a tradition emphasizing the psychometric factors that are derived from general-intelligence tests. Certainly, the skills measured by these tests are useful in many different ways (Sackett et al. 2020). But the skills have utterly failed us in terms of creating a better world, not only for our children, but also for us. As I write, many people are locked indoors by a pandemic that our IQ points appear to have been insufficient, to date, adequately to combat? Is this the best humanity can do? If this is the best we can do, then the future will not be for humans, but for viruses, bacteria, and cockroaches.

We need to develop not just general-intellectual skills, but also adaptive-intellectual skills in young people. These are skills needed to solve real problems, not artificially contrived ones. The field of intelligence has become insular, largely divorced from the insights of Binet, Wechsler, and others, that intelligence should be

about functioning in the real world, not on tests measuring arcane knowledge and skills. In some ways, it is a failed enterprise stuck in a paradigm from the early 1900s. The paradigm shows exactly what is wrong with the conception of intelligence as *g*. It is internally consistent at an abstract-analytical level, but offtrack with regard to the real-world problems the world faces today.

Intentionality

José Hugo Gonçalves Magalhães¹ and João Paulo Maciel de Araujo²

¹University of Pernambuco, Petrolina, Brazil

²Federal University of Pernambuco, Recife, Brazil

Abstract

Intentionality has been understood as the ability to think and behave in accordance with goals previously elaborated by the individual, or the teleological property of mind. In this sense, intentional mental states are typically characterized by displaying contents secondary to the achievement of cognitive and/or behavioral goals underlying the constitution of beliefs, judgments, desires, and expectations directed toward the external world or the subject itself. If, on the one hand, the philosophical interest in the theme goes back to the scholastics, in the scientific sphere, the first empirical research programs on the characteristics and functional role of intentionality for psychological functioning only started in the first decades of the last century. In this entry, the relationship between intentionality and the possible will be analyzed from the role played by intentionality in the formulation, execution, and evaluation of possible action plans. To this end, the rich intersection established between intentionality, free will, and context in determining action directions will be used as a background for the discussion of how the dimension of the possible is

established in intentional action through the interaction between intentional autonomy, free choice, and socio-contextual events. Prior to this discussion, we will present a summary of the state of the art in philosophical and scientific studies about intentionality, aiming to provide introductory information about its ontological, neurocognitive, and conceptual characterization.

Keywords

Free will · Intention · Intentional action · Intentionality · Mental states · Possible

Introduction

While we interact with the world and with ourselves, our mental states inevitably find themselves directed to some kind of content (e.g., external stimuli, thoughts, memories, emotions, internal sensations, among others). When our mental states and resulting behaviors are self-regulated, or, in other words, stem from the planning and execution of goals generated by the mind itself, it is usually understood that both, the mental content and the related behavior, are consequences of the implementation of an intentional mental state. An intentional state of mind is made up of intentions, which are self-generated goals through which we voluntarily exert control over our thoughts and actions. In contrast, unintentional mental states are usually guided by automatic responses to external stimuli (Haggard 2008). This “to intent,” “to be for,” or “to create goals” faculty of the mind is called intentionality.

Intentionality is broadly defined as the ability of mind to create cognitive plans implementing self-controlled behaviors (Miller et al. 2013). It is a highly pervasive property of mind, playing a very central role in the self-organization of behavior and in the informational integration of various cognitive systems, whether human, nonhuman animal, or artificial. In this entry we propose to discuss how the domain of intentionality is related to the possible. Initially, in the two subsequent sections, we will present the state of the art of philosophical and scientific research on intentionality from a historical and conceptual perspective.

In the last section, we will seek to discuss how the dimension of the possible is related to intentionality, considering that intentional states occur through a complex interactional dynamic linking individual to contextual factors and vice versa.

The Philosophy of Intentionality

The term intentionality was originally used by the scholastics. Later in the nineteenth century it was revived by Franz Brentano. According to Brentano (1995), intentionality is the mark of the mental. Thus, the intentionality of mental phenomena distinguishes it from physical phenomena. In other words, physical phenomena do not exhibit intentionality, only mental phenomena do. Despite many interpretations (see Searle 1983; Dennett 1981, 1996; Crane 2001; Merleau-Ponty 1962) this intentional characterization of mental phenomena formed the background of twentieth-century discussions of intentionality in the analytic and continental traditions of philosophy. Mental states like beliefs, desires, hopes, and dreams are always about something. Intentionality is related to our mental contents, i.e., to how we represent the world. Therefore, intentionality concerns the way our conscious mental states are directed to objects and states of affairs in the world.

Philosophically, current discussions around intentionality occupy a prominent place in debates in philosophy of mind. When dealing with issues such as “What is mind?,” “Which beings have a mind?,” “What is consciousness?,” the theme of intentionality always arises to ensure that beyond self-aware individuals along with a large repertoire of cognitive capacities, our thoughts exhibit this characteristic of being *directed at* or *about* something. Despite a diversity of living beings existing on our planet, science already allows us to make a wide range of distinctions between those creatures that are merely alive and those that are alive and have minds, i.e., that are conscious. Whereas a tree is just an organic being, a chimpanzee is a conscious creature that exhibits intentionality through behavior. On the other hand, we human beings not only exhibit

intentionality through behavior, but also discuss, theorize about these intentional characteristics using a sophisticated linguistic apparatus.

However, how to demarcate between creatures that have a mind from creatures that don't have a mind? This question can be asked in two dimensions, an ontological and an epistemological one. What kinds of minds exist and how do we know? (see Dennett 1996). Creatures that exhibit intentional states of mind exhibit perspective. According to Crane (2001, p. 4) “The minded creature is one for which things are a certain way: the way they are from that creature's perspective.” Talking about perspective is talking about how the world is represented for a particular species or individual. Stones, trees, molecules, gamma rays, among other natural kinds, are part of the world along with many other things that exist in our universe. On the other hand, we can say that we humans and other species with a mind have a world. From the point of view of objectivity, although this world is the same for all species, the perspectives along with the cognitive constitution of each species make this world different in many representational respects.

Despite the philosophical divergences around the concept of intentionality, something seems to be mutually agreed among philosophers, the idea that in some measure mental states exhibit intentionality. As we have seen, “hopes,” “desires,” and “beliefs” are examples that show intentional states in an individual, they are intentional dispositions to adopt a certain attitude about something. However, intentionality also has an aspect that is related to our actions. Thus, it is present in our ideas that the most common actions are consciously deliberate. Consequently, the intention to do something manifests itself as an intentional state to act deliberately in a certain way. However, the intentionality described as intentional action reveals itself only as one of the many aspects according to which we can characterize the concept of intentionality.

Searle (1983) discussed the many aspects of mental states that exhibit intentionality and made some distinctions in order not to incur conceptual confusions. According to Searle (1983) and unlike Brentano (1995), only some mental states,

and not all, have intentionality. Searle (1983, p. 1) stated that “Beliefs, fears, hopes, and desires are Intentional; but there are forms of nervousness, elation, and undirected anxiety that are not Intentional.” They aren’t because they don’t have an object. I can wake up depressed on a beautiful sunny day without, however, knowing what exactly I am depressed about.

It is very common for philosophers to maintain an identity between intentionality and consciousness, when in fact they are completely different things. Also, according to Searle (1983) it is not the case that every conscious state is intentional, e.g., the sudden awareness of a pain in the knee. Likewise, not every intentional state is conscious. I may have the belief that “hunger is a problem that has increased during the pandemic,” but so far, I wasn’t aware of this belief because I wasn’t thinking about it. These examples show us that the term intentionality is difficult to grasp and that, in general, there is no consensus among philosophers.

The Science of Intentionality

The idea that intentional capacity is a pervasive feature in the functioning of diverse cognitive systems (human, animal, and artificial) is well established in the sciences of mind and behavior since its foundational landmarks. Throughout the twentieth century, intentionality ceased to be a phenomenon of strictly philosophical interest to become, also, an object submitted to the scrutiny of the empirical sciences. Firstly, it must be pointed out that the contemporary notion of the adaptive role of intentionality for behavior and self-regulation of action is indebted to Edward Tolman’s seminal works on cognitive mapping and latent learning (Tolman 1932; Tolman and Honzik 1930).

In his classic studies with rats in mazes, Tolman showed that under different circumstances the behavior of these organisms was determined by intervening variables that influenced the stimulus-response circuit. Such variables were cognitions organized from a map, a cognitive map, whose function was to structure a behavioral

plan, including the intentions underlying behavior as a central element for action planning and control. At that moment, intentions were understood basically as pre-established expectations responsible for influencing the direction of behavior to the detriment of environmental cues presented to the experiment. That is, by suggesting that behavior can be initiated, sustained, and guided by endogenously self-generated goals (that is, the intentions itself), these findings opposed to the centrality of stimulus-based theories of behavior such as Pavlovian and operant learning in the explanation of the formation of action schemes, highlighting the importance of the role played by cognitive processes (initially conceived as “intervening variables” in the stimulus-response scheme) in the mediation of proper behavioral processes.

Historically speaking, Tolman’s studies on intentional behavior collaborated for the rise of cognitivism as a theoretical paradigm in the study of psychological phenomena in the middle of the twentieth century. In particular, the information processing theories became known for brought a prominent place to the field of intentionality in the explanation of the function and structure of mind. It is worth remembering that in the classic “Plans and structure of behavior,” Miller et al. (2013) argued that intentionality is the process responsible for predictively organizing behavior by computing information about the planning, execution, and optimization of different actions and mental operation in the context of psychophysical (e.g., sensorimotor behavior) and complex cognitive (e.g., reasoning) information processing.

The current science of intentionality is made up of different research programs. In sum, these programs are mostly interested in investigating the neural bases and interindividual recognition of intention and intentionality. Since the 1980s, we had a robust line of studies dedicated to investigating the neural mechanisms responsible for the genesis and support of intentional states. Regarding the dynamics of temporal processing of intentions in the human brain, the now classic studies developed by Benjamin Libet (Libet et al. 1983) demonstrated that a preconscious neural processing precedes the appearance of intention at the level of conscious

processing by an average time of 256 ms. In these studies, the time of brain activity that precedes a voluntary motor action (named readiness potential) was compared with the time reported by the participant, indicating the emergence of a subjective experience of “urge” (the “urging” of volition) to act or stop the intention to act. When comparing the intentional reporting time with the preparation time, it was evident that the onset of intentional brain activity was preceded by a few 100 ms by nonconscious brain activity.

Concerning the spatiality of intentionality in the brain, recent evidence indicates that circuits connecting the prefrontal activity to the pre-supplementary motor area reflect the representation of intentions in the human brain (Lau et al. 2004) as well as those of chimpanzees (Boussaoud 2001). Another well-established research program for the empirical understanding of intentionality refers to the study of its social recognition and interindividual sharing. Such research basically investigates how intentions of possible intentional agents are decoded by external observers and are especially interested in exploring how intentional activity are socially recognized and how the attribution of intentionality is performed by humans and nonhuman animals in the context of social interaction (see Tomasello and Carpenter 2007).

Intentionality, Free Will, and the Possible

From a philosophical and scientific point of view, intentionality is not a theme that develops separately. Even people who do not deal directly with this type of research notice its connection with other logical and empirical problems. There are many possibilities for dialogue with the theme of intentionality. However, perhaps the theme of free will is one of immediate themes when we consider a certain self-determined feature of intentional mental states. In fact, through different circumstances we expect that people be able to switch between different intentional states while exercising their free will, consequently, acting to modify the purpose and consequent direction of their own

actions and thoughts. Therefore, in order to develop a reflection on intentionality and the possible, we will consider the possible as the moderating dimension of free will, thus exercised by the intentional subject during their process of interaction with the world.

Free will is a commonsense notion widely shared among different cultures. It is a basic assumption in understanding the level of autonomy exercised by an intentional agent during the performance of their actions, as well as in the attribution of responsibility to such agents. *Prima facie*, from a pragmatic point of view, it may seem nonsensical to deny that we have free will. We have the feeling that we act freely all the time. However, the free will thesis has been questioned since the dawn of Western thought. Roughly speaking, there are two ways to attack the free will thesis: one logical and the other empirical. The logical form consists of a set of arguments that are known by the term “fatalism” (see Ayer 1973; Rice 2018). Fatalist arguments are not based on any kind of empirical premise; they are therefore *a priori* arguments. It will not be our aim to develop fatalistic considerations about human freedom; we will focus our attention on a brief empirical description.

The empirical form is based on the premise of determinism. According to determinism (also known as causal determinism, see Hoefer 2016) our universe is causally determined by physical laws. Consequently, a mechanistic description of the universe would be incompatible with the notion of free will. Determinism discredits that humans are free to act. Human beings are not themselves the source of their actions. Currently, this notion is based on the postulate that free will is a fiction. Our neurobiological apparatus would be responsible for producing all the processes of the mind, including free will. Endorsing determinism means sharing the belief that our actions are the result of a causal chain that belongs to the distant past. Consequently, individuals themselves would not be the source of the causal realization of their actions. Therefore, this would imply a commitment to the radical thesis that free will and moral responsibility are illusions (see Strawson 2010).

A third alternative to discussing free will is compatibilism. The compatibilist simply denies that there is any incongruity between free will and determinism. Instead, he argues that free will is compatible with determinism (see McKenna 2019). According to this view, for us human beings, no matter how involved we are in a causal chain, there can always be the possibility of stopping our action or choosing between different possibilities of action. In other words, compatibilism starts from the notion that the existence of counterfactuals in our cognitive experience supports the ontological possibility of free will, even in a world that is, at least apparently, physically determined. Thus, thinking and acting based on counterfactuals presupposes an openness to different possibilities of action, whether when the action has already been consummated or is still in the course of being consummated. In this sense, our conviction that we have free will is not so easy to abandon.

Despite being a feasible reality or a useful illusion, the concrete exercise of free will has been investigated as the achievement of actions are, at least gradually, intentionally planned and executed (see Wegner 2002). This type of endogenously guided action, that is, an action sustained by goals previously constituted by the individual, has been specifically called intentional action (see Bonicalzi and Haggard 2019). This variety of action has a different nature from reflex or involuntary actions (which are guided by external stimuli or involuntary reactions to the detriment of self-generated intentions) and constitutes a true locus of intersection between intentionality and free will, since it is an action initiated and guided a priori by the intentions of a subject acting based on their own intentional autonomy.

The forwarding of an intentional action produces in people a certain sense of causal autonomy or a sense of agency that accompanies the self-regulation of intentional action in different contexts (Moore and Obhi 2012). Characterized as the experience of generating effects in the external world through intentionally guided actions, the sense of agency (the experience of intentional action itself) can be attenuated or amplified through the interaction between two

extremes of our reality. On the one hand, we have the extreme of the external world and its factors (e.g., environment, social structure, valence of stimuli, among others), and on the other, the extreme that encompasses the processes of the intentionally sustained action by the agent itself (e.g., volition, beliefs, emotions, neurological dysfunctions, among others) (Haggard 2008). According to a recent view of the compositional character of the experience of intentional action, it is the interaction between various processes crossing the trajectory between these extremes that determines the quality and levels of such experience (see Bonicalzi and Haggard 2019). This conception understands that in the field of action, it is not always possible to have a parallel between intentions and their cognitive or behavioral outcomes, since intentions are constituted at the intersection between intrinsic (beliefs, motives, goals, volition) and extrinsic (environment, social context, norms) factors surrounding the proper experience of intentional action.

From this interactional view, we can infer that both extremes and their processes are capable of differentially and decisively contributing to the construction of the dimension of the possible at the level of intentionality, in general, and intentional actions, in particular. The expressions of the possible would thus involve a wide range of events related to the maintenance or change of the course of intentional actions according to the interaction between the intentional agent and the surrounding world. In this sense, the possible in intentionality would emerge as a space of intersection between objectives underlying the intentional behavior, other individual variables and stimuli brought by the external world. We can suppose that the dimension of the possible would emerge in the continuum of a recalibration of the direction of the subject interaction with their context when the contact with new cognitive information and environmental stimuli are sufficiently capable of producing changes in the scope of its original intentional behavior. Thus, acting as an intentional agent in a complex world would not only involve pursuing goals, but above all, mitigating possible environmental distractors, inhibiting competing internal

intentions, among others. Therefore, we can assume that the field of the possible in intentionality arises as a consequence of the possibility of materializing intentions through action in a multifaceted world, as a space open to novelty in accordance with the different situational circumstances and the subject current state and personal dispositions.

Conclusion

This entry aimed to characterize the relationship between intentionality and the possible. After presenting the state of the art of philosophical and scientific research on intentionality, we propose that the possible emerges in the scope of intentionality through the intersection between intrinsic and extrinsic factors in the consummation of intentions by an intentional agent. We seek to demonstrate that while the first factors are related to volitional aspects typically present in intentionally guided actions, such as causal autonomy and free choice, those of the second type emerge from contextual and socio-environmental events. We argue that it is from the interaction between a subject and a world that the possible emerges in intentional behavior, as a filter of intentional achievement.

Sometimes, when we carry out our goals, we achieve the exact outcomes of our intentions. Sometimes, we can voluntarily change the trajectory of our intentions when inhibiting concurrent intentions or we may simply give up or lose control of our intentions altogether by voluntarily or involuntarily adhering to the stimuli of the context and social environment around us. In any case, the dimension of the possible imposes itself on the dynamics of our intentional achievements when what is pointed out in the agential horizon, in one way or another, is the possibility of going ahead or not with our own intentions.

Abstract

This entry addresses invention from five different perspectives: (i) definition of the term, (ii) mechanisms underlying invention processes, (iii) (pre-)history of human inventions, (iv) intellectual property protection vs open innovation, and (v) case studies of great inventors. Regarding the definition, an invention is the outcome of a creative process taking place within a technological milieu, which is recognized as successful in terms of its effectiveness as an original technology. In the process of invention, a technological possibility becomes realized. Inventions are distinct from either discovery or innovation. In human creative processes, seven mechanisms of invention can be observed, yielding characteristic outcomes: (1) basic inventions, (2) invention branches, (3) invention combinations, (4) invention toolkits, (5) invention exaptations, (6) invention values, and (7) game-changing inventions. The development of humanity has been strongly shaped by inventions ever since early stone tools and the conception of agriculture. An “explosion of creativity” has been associated with *Homo sapiens*, and inventions in all fields of human endeavor have followed suit, engendering an exponential growth of cumulative culture. This culture development emerges essentially through a reuse of previous inventions, their revision, amendment and rededication. In sociocultural terms, humans have increasingly regulated processes of invention and invention-reuse through concepts such as intellectual property, patents,

open innovation and licensing methods. Finally, three case studies of great inventors are considered: Edison, Marconi, and Montessori, next to a discussion of human invention processes as collaborative endeavors.

Definition of Invention

In order to define the term invention, it is necessary first to clarify the terms technology, creativity, and creative achievement. The etymology of the term *technology* can be traced back to the Greek word *tekhnologia*, intended as the systematic treatment of an art or a craft, through a system or method of making or doing. It is important to underline that the Greeks included both the arts and crafting tools within the realm of technology. According to Corazza and Lubart (2020, p. 2), *creativity* is defined as “a context-embedded phenomenon requiring potential originality and effectiveness.” This is an evolution of the dynamic definition of creativity recently introduced (Corazza 2016), indicating that the creative process involves a search for potential originality, which subsumes the concepts of novelty, non-obviousness, and authenticity as well as potential effectiveness with respect to a specific domain of knowledge, which could correspond to a technological field, but not necessarily so. Creativity can also involve intangible ideas in abstract domains of thought. For an actor to be creative, it is not necessary to be successful in finding originality and effectiveness, but it is sufficient to pose a challenge to the state-of-the-art: the bolder the challenge, the higher the potential. It is possible for this potential to remain unexpressed, latent, or unrecognized: in this case the process remains in a state of *creative inconclusiveness*, which is a key part of the dynamic creative process (Corazza 2016, 2019, 2020; von Thienen et al. 2017). On the other hand, in relatively less frequent occasions the potential becomes realized and

outcomes of the creative process are appreciated within a cultural context: the process enters a state of *creative achievement* (Corazza 2016, 2019, 2020).

Invention can be defined as a form of creative achievement in a technological context. Therefore, invention is an outcome of a creative process taking place within a technological milieu, which is recognized as successful in terms of its effectiveness as an original technology. In other words, an invention involves bringing into existence a device, an object, a procedure, or a system that possesses characteristics of both originality with respect to already existing state-of-the-art solutions and effectiveness in terms of performing functions in a specific field of technology. Technology and invention can be discussed also from the point of view of nonhuman species (Kaufman and Kaufman 2015). In this entry, we concentrate on the human side of these entities.

When technology is man-made, so is invention. Therefore, invention is clearly distinct from scientific discovery, which involves the observation of nature and the identification of its characteristics in terms of laws, theorems, and mechanisms (Corazza and Agnoli 2018). All that is discovered in nature exists even without the intervention of the human species. All that is invented would not exist without someone's intervention.

It is also important to distinguish between invention and innovation. An invention is the outcome of a creative process, which can remain an idle outcome that does not get used in real life. In this case, the invention does not produce innovation, at least for the time being. Innovation occurs whenever an invention is exploited in real life. Very often, long time spans separate invention from innovation, such as several hundred years before an invention actually gets used in society and thus brings about innovation (Rhodes 1961). On the other hand, an innovation does not necessarily require an invention: for example, a company can undergo a process of innovation through reorganization (managerial innovation) or introducing new technologies, which are only a local novelty, as they already exist in other companies.

An invention can become a form of intellectual property when it is possible to uniquely identify the mind that carried out the creative process, where a mind can refer both to an individual or an organization. Fencing intellectual property becomes increasingly difficult the more the invention emerges from a process of co-creation.

Mechanisms of Invention

Creativity episodes are not only engendered by *Homo sapiens*, our current species. They can be found in hominin history, as well as in the so-called “biological and material layers of complexity” (Corazza 2019; Corazza and Lubart 2020). All creativity episodes are in some way concatenated, thus forming a *Dynamic Universal Creativity Process (DUCP)*, whose origin can be traced back to the Big Bang (Corazza 2019; Corazza and Lubart 2020). Since inventions are creative achievements in technological work domains, it is possible to study the specific fragment of the DUCP concerned with human technology. Looking through the history of hominin inventions, recurrent processes become evident, which we identify here as “mechanisms of invention.”

A notable characteristic of hominin inventors is that they achieve high levels of complexity and performance in novel products by reusing past inventions. Over time the creativity episodes of different inventors are concatenated, yielding a phenomenon called “cumulative culture” or “ratcheting”:

- In a resource-intensive process, *inventor A* develops an invention.
- *Inventor B* picks up *A*'s invention without investing many resources. Therefore *B* can spend his/her time and energy on further advancements in the field, engendering another, yet more complex and/or effective invention.
- After a while a level of sophistication is achieved that no single inventor could achieve alone, if starting from the origin, with *A*'s cultural resources.

Importantly, the process of invention – the creative process – tends to be time-intensive and strenuous. Before an invention finally succeeds, long phases of work are typically required where the inventor faces *creative inconclusiveness*. During these early phases, ideas and prototypes appear to be lacking in terms of originality and/or effectiveness, so the process needs to continue, before an invention can be claimed and released. Because creative processes take time and perseverance, even smart individuals cannot conceive mankind's sophisticated inventions from scratch in a single lifetime. To progress on the ladder of cultural ratcheting, inventors need to start from high-points of already available culture, generated very often over multiple generations of previous inventors.

Thus, the potential for future inventions in a community hinges in large part on past inventions. In other words, there is a sequential dependency effect (Altman and Mesoudi 2019; von Thienen et al. [in press](#)). For instance, the Internet could not have been invented without prior inventions of electrical power networks, telecommunications, and computer technology. For future prospects this means that every new invention increases the number of inventions that are likely to follow in the community, the performance of subsequent inventions (according to given criteria or development goals) and they provide trajectories for further developments, thus defining novel design spaces where future inventions can be expected. To shed further light on these dynamics, basic operations or mechanisms can be differentiated, which resurface in human invention processes, as represented in Fig. 1 (for related models, see Kolodny et al. 2015; von Thienen et al. [in press](#)). The use of these operations or mechanisms also shapes the potential of individuals and communities to make further inventions.

- (i) *Basic Inventions* are created (see boxes 1, 2, 3 in Fig. 1). For instance, in the prehistory of humanity, stone tools have been conceived. There was the invention of agriculture and wheels. Drive systems were developed based on horses and ox at earlier times, while later the motor was invented.

- (ii) Basic inventions evolve into *Invention Branches* (e.g., see boxes 1.1, 1.11, 1.12 in Fig. 1). These branches exhibit two major characteristics: diversification and refinement. For instance, motor technology has diversified into different lineages of steam, diesel, petrol, electro, and hydrogen technology. Refinement means that solutions become more effective over time – in light of a continuous value or development goal. For instance, automobile engines invented around the year 2000 had more horsepower than automobile engines invented one hundred years earlier.
- (iii) *Invention Combinations* emerge (e.g., see boxes 1 & 2, 1 & 3, 2 & 3, 1 & 2 & 3 in Fig. 1). For example, modern automobiles combine earlier inventions of wheels and motors. Numerically, with every new invention that becomes available in a community, the number of possible invention combinations that the community can probe increases factorially.
- (iv) *Invention Toolkits* get developed (e.g., see boxes 1a, 1b, 1c, 1d in Fig. 1). Toolkits serve to render the application of a basic invention more convenient and/or effective. For instance, when agriculture was conceived, toolkit-inventions such as ploughs and water management followed suit. Often the success of a basic invention depends on the emergence of a respective toolkit. Without the toolkit, typically the basic invention introduces a lasting usage possibility, but cannot be implemented and sustained for long.
- (v) *Invention Exaptations* develop (e.g., see boxes 1', 1*, 1♦ in Fig. 1). Novel uses are found for already existing technology, which can be identified as exaptations (Corazza 2019; Gould and Vrba 1982). Thus, past inventions obtain novel functionalities. Technically, design principles of earlier inventions get reused in different contexts. For instance, a basic principle of wheels is that there is something spinning around an axis. This principle can be reused to invent a windmill.

Invention, Fig. 1 Mechanisms that underlie human inventions, cumulative culture and ratcheting

(vi) *Invention Values* are extracted, maintained, or dynamically changed (Corazza 2016; von Thienen et al. [in press](#)), (e.g., see boxes 1- α , 1- β in Fig. 1). Inventions convey values and elicit value reflections. When values stay constant, trajectories of invention development are stable and incremental innovation is stimulated. Thus, in the twentieth century the automobile industry that constantly valued maximal horsepower produced incrementally innovative automobile engines. Novel motor inventions resembled past motors, only details were changed and horsepower increased. By contrast, when values change, disruptive innovation gets stimulated. The search space for novel solutions opens up and inventions in many different directions get probed. For instance, in recent years, the value of eco-friendly solutions became prominent. This did not only open up the search space from existing automobile engines to radically different motor technologies, but even novel mobility solutions beyond automobiles became sought with ample efforts. Notably, values can

inform creative developments in more than one knowledge field; e.g., the value of eco-friendly solutions can shape creative processes in domains as different as the automobile industry and agriculture. It is also possible that novel inventions cause societal value changes and disruptive innovation follows suit. For instance, pioneers of modern art invented novel painting techniques based on abstract representations. Their personal values informing the inventions became more broadly accepted over time and thus a novel art epoch was inaugurated.

(vii) Finally, inventions can be used as game-changers, to facilitate creative developments in the future. For instance, the inventions of writing and the printing press were game-changers for subsequent creative developments (Kolodny et al. 2016). With printed records, every new invention can be documented much better and knowledge about inventions can be communicated across more individuals. Thus, there is much less knowledge loss over time.

Subsequent generations of inventors benefit more from inventions that had been made in the past.

Inventions Across Human History

The history of hominin inventions begins with the outset of cumulative culture. It is a history that goes back to times when the *Homo sapiens* was not yet existing, and other hominin species populated the Earth. Archaeological records indicate that the onset of hominin cumulative culture occurred already millions of years ago (Enquist et al. 2008), evidenced by basic inventions evolving into invention branches, ever more diverse and refined over time.

Stone tools are among the earliest hominin inventions. Specimens found at Lomekwi 3 in Kenya have been dated as far back as 3.3 million years ago (Harmand et al. 2015). Over several million years, hominins have invented an exponentially increasing number of different stone tools in a continuous process of diversification: While in the Oldowan period, about two million years ago, hominin inventors seemed to produce less than 10 different kinds of stone tools, in the Upper Paleolithic, beginning roughly 50,000 years ago, hominin makers had invented about 70 different types of stone tools (Lehman 1947; Enquist et al. 2008). While early on hammer and chopping stones were used, later more diverse stone tools were invented, including bracelets, axes, polishing tools, and harpoons. Along with diversification, refinement occurred. Early chopping stones were much rougher than its sophisticated counterparts two million years later. This improvement was rendered possible by ever more refined technical strategies in the production of stone tools (Stout 2011). Some of the increasing sophistication can be understood in light of a continuous value of surface smoothness, so that over time stone tools showed reduced rates of accidental irregularities.

Another early invention in humanity's (pre-) history was agriculture, ca. 12,000 years ago. It entailed huge changes to physical and social environments (Altman and Mesoudi 2019). Notably,

agriculture increased food availability, which allowed population sizes to increase. This, in turn, permitted a greater diversification of societal roles and knowledge domains. With each new knowledge domain, the cultural "raw material" for subsequent inventions increased.

Another important field of creativity was law, which is closely linked to the emergence of civilizations – known hotbeds of invention. Laws had already been invented several thousand years BC, as documented in Ancient Egypt. Important further developments were made, for instance, in the Roman Empire, where detailed rules were developed by professional jurists, and sophisticated forms of codification were engendered.

On a coarse glance the pace of innovation seems to be increasing exponentially over time (Enquist et al. 2008). However, on a closer look there are phases of slow change or continuity, intertwined with phases of "creative explosions," where numerous novelties emerge in short order (Kuhn 1962/1970; Kolodny et al. 2015; Kuhn 2012). The Industrial Revolution beginning in the eighteenth century has been such a creative explosion. It was a period of transition from hand-production methods to increasing automation and use of machines. It brought about novel business organizations such as mechanized factory systems, next to novel social roles and professions. Like the invention of agriculture, the industrialization had a huge impact on demography. Due to the increased availability of everyday supplies through automated production, population sizes increased drastically. Once again, greater numbers of people imply a greater potential for knowledge diversification – one driving factor of cumulative culture.

Intellectual Property Protection Versus Open Innovation

In the realm of socio-legal frameworks, key inventions have been made to guide the publication and reuse of inventions. Thus, processes of ratcheting and cumulative culture development were not left to chance or dynamics of nature any longer, but became regulated in terms of

permissions and prohibitions. Within law, rubrics emerged that concern invention in a straightforward way, as they address questions of intellectual property. In socio-legal realms, conceptual developments included patenting, copyright, open innovation, open content initiatives, and Creative Commons licenses.

A patent is a form of intellectual property. It gives the patent owner a time-limited right to exclude others from any commercial use of the invention, including producing, selling, offering for sale, and importing. The patent owner can grant such rights to others, usually based on remuneration. To obtain a patent, first, the invention must relate to patentable subject matter. E.g., if a plant shall be patented it must not be a naturally occurring plant but a plant with traits produced through technical means (Metzger and Bartels 2018). The invention must also be novel, nonobvious, and susceptible of industrial application. Second, the invention must be disclosed and published. Patent protection serves to ensure that creative processes “pay off” for the inventor, specifically when (i) creative achievement is extremely resource-intensive to produce, while (ii) resulting inventions can be copied easily by others. For instance, the development of a novel and effective medication may need the work-time of many researchers in a company, costly equipment, and hundreds of test patients. However, once the company has found an effective recipe, other organizations might copy the product easily. Moreover, since these other organizations had no costly research to inform their pricing model, they might sell the product for a lower price, so that the inventor-firm would barely benefit from their creative work. Thus, securing benefits for the inventor in case of creative achievements is one key political approach to foster cost-intensive creative developments. Historically, early patent systems were already used in Ancient Greece. The Venetian Patent Statute of 1474 is regarded as the first statutory patent system.

On the other side, inventors can also have straightforward interests to spread their solutions, instead of selling a limited number of usage-permissions. For instance, the quality of

scientific work is often measured by numbers of citations, so scientists benefit when they render their inventions of methods, concepts, and theories openly available for others to cite and reuse.

In the pursuit of *open innovation*, companies engage in idea exchange with other companies and creative customers. Thus, a wider range of expertise, manpower, and creative-collaborative enthusiasm can inform developments. The creative potential of a population increases with numbers of ideas that are available for recombination (cf. mechanisms of invention), and with different minds, perspectives, and expertise that come to play together. Therefore, involving more persons with varied backgrounds in creative processes by means of loose collaboration networks increases the creative potential of the overall group and individuals herein (Derex et al. 2016; Dean et al. 2014).

Creative Commons licenses provide tools for the sharing and reuse of creative works. By means of standard license agreements, authors can allow the public to reuse creative works in ways that normally would be prohibited due to copyright protection. Different licenses are available, so that authors can communicate specifically which rights they reserve and which rights they waive. While copyright law itself is a relatively recent legal development, emerging in statutory terms only after the invention of the printing press, the development of Creative Commons licenses is an even more recent phenomenon with the charitable organization issuing these licenses founded in 2001.

Overall, socio-legal systems that guide cumulative culture development and ratcheting have themselves undergone processes of cumulative culture development and ratcheting. Human cultures are thus changing parameters of their own development, organizing and reorganizing concatenations of invention from scratch. In a straightforward sense, what is possible for inventors in a society depends on the state of culture development in that society, including legal regulations that permit or prohibit the reuse of other people’s ideas. One next step will be to address the difficult regulation of intellectual property produced by artificial intelligence.

The Mindset of Great Inventors

When dealing with inventions, important lessons can be drawn from eminent examples of the past. One of the world's most famous inventors is Thomas Alva Edison (1847–1931), who was awarded over a thousand patents in his lifetime (Wills 2007). He vigorously thought about applications of physical phenomena such as electricity and electromagnetism to provide novel products and services, leading him to make ample contributions in fields such as mass communication, energy supply, sound recording, and motion pictures. In his work, he followed a structured process of trial and error, where many different combinations and setups were probed. His creative processes often endured for long times, and it was perseverance that rendered creative achievement possible in the end. One example is Edison's invention of an early version of a light-bulb. It is reported how "in his search for the best material out of which to make his incandescent filaments, he tried over sixteen hundred different materials, even including Limburger cheese" (Arnold 1959/2016, p. 73). The immense workload of such creative processes was mastered by Edison together with large teams. While Edison's staff sometimes expressed frustration after numerous unsuccessful trials, he highlighted the knowledge gained in the process and that continued exploration would be the route to eventual success. Edison's approach to invention is thus a key example for long phases of *creative inconclusiveness* prior to eventual achievement. His case also shows how a clear cognitive model of the creative process can be game-changing. Without his understanding of how to conduct creative processes, what difficulties to expect along the way (such as numerous failed trials and ensuing frustration) as well as means to overcome the difficulties (perseverance and learning from failure), Edison's portfolio of inventions would not have emerged as it did.

Another notable case is that of Guglielmo Marconi. Since he was an adolescent, Marconi developed the vision of working as an inventor. Backed by his family and supported by a personal tutor, he pursued education in early applications of electromagnetism, the "hottest" technical topic at the end

of the XIX century. Notably, Marconi never attended a university, which adds to his merits in being awarded a Nobel Prize in physics in 1909. When he performed his first experiments that would lead to the invention of wireless telegraphy in 1895, Guglielmo Marconi was just a 21-years old young man playing around with ideas at Villa Griffone, near Bologna (Italy). The ensuing history of the refinements of his invention was driven by the quest for ever-longer distances of end-to-end communication, up to the triumphant crossing of the Atlantic Ocean on 12 December 1901, when Marconi was 27-years old. This transatlantic experiment was carried out against the solid opinions of leading mathematical-physicists of the time, who presumed to have proven that this transmission was impossible. What nobody knew, including the young Guglielmo, was that the Earth is surrounded by the ionosphere, a layer of plasma generated by the impact of sun energy onto our atmosphere. It is often true that, for disruptive inventions, intuition comes before proof. Marconi went on to develop many other applications of radio transmission, including broadcasting, radio navigation, directive antennas, and he developed in 1935 a clear vision of what would become personal communication technology in the future. Great inventors are often able to read further into the future than others. At the time of Marconi many scientists and technologists worked on radio devices. What distinguished him from others was his vision for the overall system and its innumerable applications, which he successfully pursued as a young entrepreneur.

We finally consider the case of Maria Montessori, which is of interest not only for the outcomes of her creative processes, but also for the obstacles she had to overcome. Born in Chiaravalle (Ancona, Italy) in 1870, she faced strong societal expectations as a woman in the Italian society of the nineteenth century. However, early on she showed a unique determination to pursue scientific studies and a respective career. Resisting different forms of discrimination, she achieved a degree in medicine, specializing on neuropsychiatry – the first woman in Italy in this field. Her attention turned to poor children, who at the time could not receive an education and therefore grew up in analphabetism, developing social inaptness,

so much so that many of them ended up hospitalized in psychiatric institutions in their childhood. In the “Quartiere San Lorenzo” of Rome, Maria Montessori built “La Casa del Bambino,” an institution devoted to the education of these neglected children. Here she invented, probed, and refined educational tools that would later become an integral part of the Montessori Method. These inventions were disruptive as they countervailed traditional educational methodologies. At first they were received with skepticism and scorn. But Maria Montessori achieved outstanding results: Thanks to her new educational methodology, poor children – considered “insane” before – were able to successfully pass the exams for the primary school license, which had been thought impossible by many contemporaries. The tools and the class environments that Maria Montessori invented anticipated by several decades modern theories of embodied and embedded cognition, a further testimony to the observation that a great inventor is typically also a great visionary.

Case studies like these elucidate recurrent characteristics of inventors, which often include boldness, vision, intuition, and perseverance. Such observations fall well in line with analyses of creative processes. Widely recognized human inventions tend to be complex and, by definition, inventions are novel, which means that inventors need to explore and build up novel terrain. Creative processes are therefore learning journeys and inventors need an empowering mindset to endure (usually long) phases of *creative inconclusiveness*, where their work domain contains many ambiguities, first trials fail and society may react with skepticism or mockery – prior to creative achievements. Here the inventor’s mindset is among the core determinants of what becomes possible for the person.

While such individual journeys of invention can be studied and analyzed, it is clear at the same time that creativity episodes of different human inventors are concatenated. In this sense, later-coming inventors typically do not develop everything from scratch, but they rethink and recombine many inventions made by others before. Invention as observable in hominins, with notable trajectories of cumulative culture development, is essentially collaborative. In this sense, there is an

implicit collaboration between later-coming inventors and their predecessors. Moreover, many inventions are straightforwardly produced through collaboration – as in the case of a space rocket, where the overall invention could only be produced collaboratively, with many team members contributing smaller-scale inventions concerning parts of the system. Collaboration and the concatenation of creative processes enable highly complex and sophisticated inventions that go beyond the inventive abilities of a single person.

Irony

Michael Hanchett Hanson
Teachers College, Columbia University,
New York City, NY, USA

Abstract

Irony has been conceived and studied in different ways across history and disciplines – as a trope, sensibility, stance, cognitive structure,

and worldview. Some philosophies have argued that irony is at the heart of all meaning, a way of overcoming limitations of meaning through those very limitations. These various concepts have, in turn, defined multiple and complicated relationships to people's conceptions of the possible. Irony can undermine rigidity, hypocrisy, blind faith, and other knee-jerk responses, thereby opening new conceptual spaces. Irony preys on excesses of all sorts, though, including the irrational exuberance that can accompany new possibilities and any claim to certainty about the future. In these dual opening and constraining functions, irony can enhance other thought processes and, in some cases, provide a logic of its own in producing new ideas.

Keywords

Discursive communities · Final vocabularies · Irony · Literature · Philosophy · Postmodern irony · Romantic irony · Situational irony · Verbal irony · Worldview · Zeitgeist

In 1729, Dr. Jonathan Swift published *A Modest Proposal For preventing the Children of Poor People From being a Burthen to Their Parents or Country, and For making them Beneficial to the Publick*. After describing the desperate plight of the poor and starving in Ireland, Swift describes his “solution”: the Irish should sell their children as food. “A young healthy child well nursed, is, at a year old, a most delicious nourishing and wholesome food, whether stewed, roasted, baked, or boiled; and I make no doubt that it will equally serve in a fricassee, or a ragoust”. The essay goes on at length concerning the practical and statistical advantages of the proposal, skewering English attitudes toward the Irish and class divisions – “I grant this food will be somewhat dear, and therefore very proper for landlords, who, as they have already devoured most of the parents, seem to have the best title to the children” – while parodying the social-engineering solutions to economic problems in vogue at the time.

In early times, all stories belonged to the sky god Nyankonpon. But the spider Anansi wanted

the stories and asked to buy them. Nyankonpon laughed because many great cities had tried to buy the stories and could not. A mere spider could never pay the price, which was a python, a leopard, wasps and a fairy. But Anansi consulted his wife, Aso, and the two found ways to outwit all of these prizes, using the victims' vanity and/or their own power against them. Anansi bound them in his web and delivered them to the sky god. Thus, stories became known as spider stories. One of them is this story.

(Summary of Ashanti myth. See, for example, Rattray 1930)

Scholarship on irony spans several disciplines and a wide range of definitions. Irony can be seen as a trope, sensibility, stance, cognitive structure, worldview, and/or a dynamic of meaning in general. All conceptions, though, involve the possible.

- *Multi-perspective structure.* Most fundamentally, irony tightly juxtaposes alternative ways of seeing a situation, establishing that there *are* multiple points of view. Among those views, irony undermines the assumptions or certainties held by at least some people. In practice, this redirecting of attention can range from gentle prods toward the more complex to derision of the foolish. Ironic ways of seeing a situation or the world in general can, thus, contribute both to the perception and production of new perspectives, even as the judgmental edge of irony undermines the validity of others.
- *Social dynamic.* Irony is social, both reflecting and recruiting to discursive communities. Winking is not enough. Someone has to “get” the irony (us – both reflecting communities and recruiting to them), and someone is always a victim or target (them). Both roles construct community boundaries. Even private appreciation of irony situates the one perceiving the irony in imagined relation to differing communities of knowledge, practice, and/or values.
- *Ongoing dynamic of meaning.* Irony is not necessarily an isolated view amid a sea of analytic arguments, sincerity, and convention. Irony has also been conceived as fundamental

to all meaning and/or as a way of surmounting the inadequacies of language and other representational systems (e.g., Rorty 1989; Schlegel 1798–1800/1991). In the process, irony continually redirects attention to the more general and abstract, an ongoing surmounting of ironies on top of ironies.

In all three of these conceptions, the ironic stance to the world is linked to the possible as an exceptional event within, or as a condition of, meaning.

A Working Definition

Amid the diversity of perspectives and categories, patterns of consensus have emerged. Taking into account a wide array of scholarship (including, Colebrook 2004; Hutcheon 1994; Lucariello 1994; Meucke 1969/2020; Wilde 1981), irony can be defined as *seeing a situation in particular ways that emphasize contradiction or incongruity with a judgmental edge*. These views of the situation match types of circumstances that are socially recognized as ironic (situational irony), and people may reference such situations through juxtapositions of literal and intended meaning (verbal irony). The judgmental edge orients the stance away from the perspectives targeted by the irony and, implicitly or explicitly, toward other views. Seeing the irony requires sophistication (Hutcheon 1994; Meucke 1969/2020), meaning that irony is built on knowledge of context and expectations, and greater knowledge of relevant history, conventions, nuance, social dynamics, and so on tends to afford greater possibilities of irony.

A particular irony may, then, be seen as anomalous to broader experience – hypocrisy, foolishness, or *schadenfreude*, for example – or indicative of broader reality – cosmic, existential, romantic, or postmodern irony. Consider, for example, a few famous ironists: Lao Tzu, Socrates, Jonathan Swift, Rabindranath Tagore, George Bernard Shaw, Jane Austen, Virginia Woolf. Some consciously embraced a form of irony as worldview – Lao Tzu's view of the Tao as

constant flux of opposing forces (yin and yang) or Socrates's insistence on ignorance as the path to wisdom. Others may simply perceive and emphasize irony often as in Swift's attacks on hypocrisy and foolishness or the plot twists in Tagore's short stories or Austen's critiques of English manners. Sometimes, the specific and general mix, such as Woolf's use of irony in relation to gender and sexuality, targeting specific beliefs and practices, presented with ironies of consciousness itself in her literary style. And, sometimes, the specific leads to the general as in Shaw's view of World War I as the product of foolish politicians in 1914 but as an example of inevitable ironies of nature at the end of the war (see discussion below).

Typological Controversies

The working definition above is intentionally broad, and a range of theorists would agree with it in large part. But when those theorists get to detailed typologies – and they often do – there is still plenty of room for disagreement. Sarcasm – saying the opposite of what is meant with strong condescending affect – may be treated as central to the idea of irony because it is marked so obviously or as a limit case because of the same lack of nuance. Paradoxes, loops where ideas lead to contradictory, absurd, or impossible conclusions (e.g., “this statement is false”) may also be classified as a limit case of the larger category, irony, or as a related but separate phenomenon. Satire and parody are often treated as literary genres for which irony is the central trope but can also be cited as simply examples of the, again, larger category of irony.

Multi-Perspective Meaning

One of the most influential of such typologies has been D. C. Muecke's *Compass of Irony*, originally published 1969 and republished in 1980 and 2020. Muecke began by describing irony as being like mist, easy to see but too nebulous to take in hand. He, nevertheless, took on the task with gusto, providing one of the most comprehensive typologies of irony in the field. His general definition of the topic was “a double-layered or

two-story” (op. cit., p. 19) structure of meaning in which the levels of interpretation of the situation are opposed as “contradiction, incongruity or incompatibility” but a “victim is confidently unaware of the very possibility of there being an upper level or point of view that invalidates his [sic] own or an ironist pretends not to be aware of it” (op. cit., p. 20). Muecke, thus, began with multiple perspectives on meaning and the social dynamic – victim and ironist roles.

He went on to define the three broad categories in his typology which were cited in discussion of the working definition, provided earlier: general irony, such as cosmic irony, and two types of specific irony, situational and verbal. Romantic irony (irony as dynamic of meaning) was his fourth large category. The typology included five types of situational irony (simple irony of incongruity, irony of events, dramatic irony, irony of self-betrayal, irony of dilemma), three grades of verbal irony (overt, covert, private), four modes of verbal irony (impersonal, self-disparaging, ingenu, dramatized), and five types of general irony (general irony of events, general dramatic irony, cosmic irony, ironies of inevitable ignorance, ironies of art). Muecke emphasized, however, that all irony ultimately refers to situations and concluded that, whatever form irony takes, it reflects a stance toward the world.

Breadth of Function

Many later theorists cited Muecke, and a number considered one or more specific aspects of his typology for further focused analysis. The primacy of situations to all forms of irony has been a particularly rich insight for elaboration by others. For example, Muecke noted that, not only is all irony ultimately grounded in perception of situations, with sophistication a viewer may be able to see any situation as ironic. There is latent irony in any experience. Linda Hutcheon (1994) built on this insight in her analysis of how “irony happens” (op. cit., p. 12). With sufficient knowledge of any situation, the perceiver may see irony. Irony's judgmental edge can then serve many purposes, depending on context and intent of the

ironist, such as aggregative (helping define communities, emphasizing inclusion or exclusion), oppositional (from transgressive, subversive to insulting), provisional (from demystifying to duplicitous), distancing (from offering new perspectives to being indifferent), complicating (from introducing rich complexity to misleading through imprecision or ambiguity), and so on. In each of the functions listed above, the emphasis tends toward finding new possibilities at one end of the scale and foreclosing possibilities at the other. Even the erudite insult or obfuscating ambiguity can, however, suggest new orientations. The functions of irony are both highly contextual and dynamic, seldom affording hard-and-fast rules.

Scripts and Expectations

Joan Lucariello (1994) also built on Muecke's point about the situational anchoring of irony. She examined irony as a socially learned, conceptually coherent way of understanding certain types of script anomalies. Jean Piaget (Gruber und Vonèche 1995) and other theorists (e.g., Schank und Abelson 1977) have found that people learn concepts and behaviors in schemas or scripts. Normally, one thing follows another in a predictable sequence with concepts related to one another in conventional ways. For example, going to a fast-food restaurant usually follows a predictable script, such as standing in line, ordering from a counter, paying, picking up the food, and seating oneself. In a fine dining restaurant, the roles, events, and order are different.

Lucariello asked subjects to produce accounts of specific types of ironic situations, adapted from Muecke's typology, and to categorize ironic situations they were given. From that research, she concluded that situational irony constitutes a distinct event-based knowledge, linked to the non-ironic scripts as deviations. Ironic scripts, however, match learned types of conceptual coherence that distinguish them from simple anomalies. Note also: sophistication is still necessary. The person must know both the non-ironic script and the type of ironic deviation to perceive the irony.

Ironic Logic

Lucariello's work helped establish the conceptual coherence of irony, but her experiments looked only at isolated examples of irony. What happens when that conceptual coherence influences a larger system of thinking, such as a person's point of view, over a longer period? There, irony can produce its own logic. Once one part of a script is flipped, perception of possible outcomes can change, which then affect other scripts for which those outcomes are context. In addition, the later events are also subject to ironic twists to their scripts.

For example, war is conventionally seen as a conflict between different nations, against *other* people, in which one side wins and the other loses. In the first months of World War I, Bernard Shaw (1914/1931) twisted that script in a number of ways as he thought through the short-and long-term consequences of the conflict. His long essay, "Common Sense about the War," used irony at almost every turn (Hanchett Hanson 2004, 2005). The English had for generations been taught to hate German *Junkers* – aristocrats – but no place produced aristocrats as well as England. Indeed, the British royal family were not just aristocrats like the German Junkers they were fighting, the British monarchs *were* German Junkers (the British royal family changed its name from Saxe-Coburg-Gotha to Windsor during the war because of the embarrassing irony). Once the soldiers understood that their enemy was not another nation but a class system, in an "ecstasy of commonsense" (Shaw 1914/1931, p. 20), they should throw down their weapons and go home to start a revolution. That outcome was unlikely, and did not occur. Using similar ironic logic, though, Shaw produced in "Common Sense" a work of amazing prescience. At a time when many thought the fighting would last only a few months, he predicted a long and bloody war that would only be resolved when America joined the fight. He predicted a second war if the terms of peace were not just and that the longer-term enemy of Western Europe would be Russia, not Germany. Shaw also prescribed a mutual defense alliance between Britain, France, Germany, and the United

States as the means to enduring peace in Europe: an outline of what would be the North Atlantic Treaty Organization (NATO). All of that would come to pass later. By the end of the war, though, Shaw (1919) himself had changed his ironic perspective. Taking the view of cosmic irony, he came to see such disasters as inevitable outcomes of human nature, which included his own political work before the war. He was still an ironist but through further ironic logic had come to a different point of view concerning causes and effects.

Social Dynamic

Roles and Expectations

Irony is grounded in the perception of situations, as described above, and the ironic twist to a situation brings with it specific roles. In ancient Greek theater stock characters included the *eiron* and the *alazon* (Frye 1957; Muecke 1969/2020), the latter, exhibiting overconfidence ranging from naiveté to arrogance to buffoonery, was the prey of the former who burst the bubble of unrealistic expectations. Someone, at least in concept, must hold such expectations. Someone must slyly point out the naiveté, rigidity, hubris, folly, illogic, and so on, and someone must get the irony. The roles victim(s), ironist, and audience are not always different people, however. For example, in self-deprecating irony, the ironist and the victim are the same person. In cosmic irony, the victims and audience are the same, with the dynamics of life itself being the ironist, pulling the rug out from under expectations. When one person uses irony in a conversation with another, the victim may not be actually present but believed to exist. A person quietly savoring an irony, without saying anything, imagines that at least some other people would also appreciate the irony and that the victim and others of that ilk would not.

These roles, built around expectations, realities, and differing levels of sophistication, must also involve conflicting views of possibility. But the ironist's judgment is not necessarily right. In the long term, the victim may get the last laugh. Such failure of the ironist position can, however, be seen as further irony, an indication of how far

the ironic perspective can go (the dynamics of meaning, discussed later).

Discursive Communities

In keeping with the criteria above, irony can also be seen as defining the background assumptions of a community or political position. This was another point that Hutcheon (1994) emphasized. The sophistication that allows irony to “happen” is not simply individual but comes from membership in discursive communities. Hutcheon used examples of perceiving irony in art and music where knowledge of the history and traditions of the art forms – being part of those discursive communities – lead viewers to see ironic references. Note that, here, irony is still anomalous, not a view of how the world necessarily works, but can become plentiful in the aspects of the world where people have sufficient contextual understanding. Similarly, Dannagal Goldthwaite Young (2020) has argued that irony and outrage play parallel roles in managing frustration – and, thereby, characterizing communities – the left tending toward irony and the right, toward outrage in current American political discourse.

Zeitgeist and Worldviews

Lucariello helped establish the principle that at least some forms of irony can be socially transmitted – learned – and Hutcheon and others have looked at how irony defines discursive communities and recruits people to them. It is not surprising, then, that irony can help define a sociohistorical period or *zeitgeist*.

An influential analysis of ironic *zeitgeist* was Northrup Frye's (1957) literary criticism. Frye's broad views of irony were part of his larger challenge to the focus of the New Criticism movement on works as purely aesthetic-linguistic objects outside of historical context. Elaborating on Aristotle, Frye analyzed narrative modes according to the relationship of the protagonist to nature and other people, positing a historical cycle from dominant mythic modes (gods above nature and people in kind) to romantic (heroes above nature and people in degree) to high mimetic (the extraordinary hero but often with a fatal flaw – subject to nature but greater than other people in degree), low mimetic

(the everyday person), and ironic (protagonists presented as less than other people, underdogs, such as the film noir detective). Although only one of the modes is labeled ironic, defined by context and tone rather than linguistic wit, Frye saw irony as also important in the other modes. For example, *lack* of irony makes the death of the romantic hero, like Beowulf, elegiac – heroism without irony – but the fall of the great high-memetic hero is necessarily “ironic in reference” (op. cit., p. 37). The narrative emphasis of his own time in the mid-twentieth century was ironic, but within this mode was the re-emergence of the mythic in works (ironic myths) like those of Franz Kafka and James Joyce.

For Frye, the mimetic and ironic narrative modes were modern, but his focus was not specifically on the break in sensibility characterized as modernism or the generation of postmodern responses. Other theorists have placed particular importance on these breaks in relation to irony. For example, Shaw was not alone in applying irony to World War I. Analyzing World War I memoirs, Paul Fussell (1975/2000) has argued that the Great War marked a general shift in modern consciousness from one of a “Meliorist myth” (op. cit., p. 8) of progress to irony as the “dominating form of modern understanding” (op. cit., p. 35). Although he described the irony that came out of the war experience as modern, Fussell was also analyzing the path to the postmodern irony.

Following that path, Alan Wilde (1981), like Frye and Fussell, examined the intersection of narratives, history, and irony. He found three “modes of consciousness” (op. cit., p. 2) in irony – pre-modern (mediate irony), modern (disjunctive irony), and postmodern (suspensive irony) – relating to three sets of assumptions about truth and reality. In the pre-modern, illustrated by authors like Chaucer or Swift, truth may be obscured by naivete, hypocrisy, deceit, or foolishness, and it is the job of irony to pull back the veil, revealing truth. Modern irony, according to Wilde, tended toward paradox, illustrated by authors like Woolf. Truth was an enduring tension between alternative views of reality that could be lived and brought to aesthetic closure but not fully resolved. Wilde then anchored postmodern irony in the existential phenomenology of Merleau-Ponty (e.g., 1964), with

truth to be found in direct experience. The irony came in the juxtaposition of experience to theories about reality, especially the typically modern transcendent narratives like those associated with Adam Smith, Karl Marx, Sigmund Freud, and so on. Among the prototypical authors of this post-modern irony was Donald Bartheleme whose short stories often made fun of hamstringing paradoxes of modernist visions of reality in contrast to the direct, everyday pleasures of life.

Dynamics of Meaning

Romantic Irony

To this point, the discussion has dealt with specific ironies, distinguishing one event from the norm, or general ironies of *zeitgeist* or worldview that, though broadly applied, still distinguish particular times and places from others. The idea of romantic irony aimed higher, though still rooted in a specific time and place. Romantic irony was defined initially in a single publication, *The Athenaeum*, by a few German authors over the 2 years of the publication’s existence, 1798–1800. Building primarily on the works of Frederick Schlegel (1798–1800/1991), one of the *Athenaeum* contributors, the concept of romantic irony has since spread and continues to be relevant (Colebrook 2004).

Representations in art always point to meaning beyond the immediately evident – a painting is not just color on canvas but represents other meaning; a character’s actions on stage or in a novel have meaning about the character, plot, and so on, beyond the mere action; and the words of poetry evoke feeling and thoughts beyond the technical meanings of the words. Muecke called this the general irony of art. It is a core element of romantic irony, but the romantics were going even further, seeing such incongruities as an ongoing dynamic among artists, their art, and its meaning. In the romantic view, people are god-like in their abilities to self-create, and artists’ minds are free to venture into any thought. Any work of art is limited, however. Therefore, the artists must both produce the work and transcend it to think anew. The work itself should reflect this dynamic,

presented with ironic self-consciousness as something to be, at once, taken seriously and transcended by the audience. In producing work, artists are, thus, satirizing the very work produced. Schlegel (1798–1800/1991) described this relationship as “transcendental buffoonery” (op. cit., p. 6, fragment 42).

Muecke (1969/2020) used Peter Weiss’s 1964 production of *The Persecution and Assassination of Marat as Performed by the Inmates of the Asylum of Charenton under the Direction of the Marquis de Sade* as a modern example of romantic irony. The play presented a series of simultaneous and incongruent contexts: the actual assassination of Marat in the eighteenth century, de Sade’s play about it, the performance in the asylum, and the 1964 production. The meaning of many lines would be different in these various contexts, and whether a line even belonged to the supposed play by de Sade or the improvisations of the inmates or of the actors now on stage was often unclear. At every point the limitations of the art were at the fore, simultaneously presented and satirized. In using this example, Muecke emphasized the ongoing relevance of romantic irony well beyond the romantic era.

Concerning the romantic view of the artist’s “transcendental buffoonery,” Muecke used an analogy of a clown tightrope walker at a circus. The professional tightrope walker walks solemnly across the treacherous line, but then the clown’s buffoonery feigns fear, nearly falls, falls and is caught by the rope, and runs to the end. Of the two, the clown must be by far the more skilled artist.

Art may have been the inspiration for the theorists of romantic irony, but they also knew that the implications extended to life more generally. If meaning is characteristically stable, then specific ironies marking script anomalies of naivete, hypocrisy, arrogance, and so on would be sufficient. If, in addition, cosmic ironies applied and consistently undercut the efforts of humans, irony would also mark recurrent frustration as a constraint on human possibilities. In describing the breadth of romantic irony, Claire Colebrook noted, “If, however, all life were instability, process, becoming and creation, then irony would be the very truth of life” – irony as the way to surmount limits

through the limitations themselves. Even the self is not fixed but a process of creation and expression, making irony “the only true mode of life” (Colebrook 2004, p. 52) in the romantic view.

Final Vocabularies

Romantic irony has been cited as a precursor to later postmodern theories (Colebrook 2004; Wilde 1981). It is not surprising, then, that postmodern theorists emphasized the power of irony (e.g., Hutcheon 1994; Lemert 1992; Venturi 1977; Wilde 1981). For example, the postmodern pragmatist Richard Rorty (1989) called for the use of irony to address limitations of the final vocabularies by which people evaluate and justify their behaviors and the behaviors of those in their communities. Vocabularies are *final* in that their value is assumed and cannot be explained except circularly. Yet these vocabularies define truth, right, good, bad, and so on. They are not just tools but constitutive of people.

Ironists have radical doubts about their final vocabularies and take an ironic stance toward this fundamental aspect of themselves and their worlds. Here, Rorty aligned with Muecke’s contention that all situations contain latent irony and Hutcheon’s view of irony “happening” with enough sophistication. Rorty was explicitly political, however, calling for people to be ironists as a stance toward the contingency of meaning and in service to social solidarity. His imperative to irony in support of social solidarity was, in effect, a call to some of the functions of irony that Hutcheon identified but not others. At the same time, his philosophy was in many ways in line with the romantic view of irony as continual recognition and engagement with the limitations of both meaning and self, an engagement intended to use the very limitations of meaning to move beyond them.

Conclusion

At this point many links between irony and possibility are apparent. First, the structure of ironic meaning, necessarily holding contradictory views of a situation in tight juxtaposition, requires

acknowledgement of multiple perspectives. Then the function of irony in undermining expectations – often blind assumptions – can open up a space for new possibilities. And, in some cases, irony can produce a kind of logic that generates unexpected insights about new possibilities. At larger scales, irony can influence and characterize discursive communities and periods of history. These world-views have at times highlighted the pervasive presence of contradiction, incongruity, and contingency – the raw material of irony – in the dynamics of meaning itself.

Irony's judgmental edge is also important. The ironist takes a critical stance, whether seen as temporary corrective, as understanding of the world, or as a way to circumvent the limits of meaning. Irony does not facilitate mere possibility but always both possibility and evaluation: perception as well as orientation. At the extreme, romantic irony describes an ongoing surmounting of irony upon irony, but at each level the judgmental edge of irony orients the meaning at hand and points to further irony, an ongoing re-orientation, reflected in the title of Muecke's (1969/2020) book, *The Compass of Irony*.

To conceptualize the possible without irony risks dichotomizing the extant and the possible in simplistic terms. The cutting edge of irony can undermine attachment to what is or might be, and the broader views of irony remind us that no meaning is absolute or static. There are always other perspectives, values, and meanings to consider. Even on irony itself.

Jazz

Marquis' Brannndon McGee
The Soundsmith Guild, Geneva, Switzerland

Abstract

To describe any musical tradition or genre solely as the summation and analysis of its musical notes and compositions may be a disservice to the wealth of knowledge, history, and cross-disciplinary lessons to be learned from it. There may be no other musical styling that this rings more true for than Jazz. In some regards, Jazz could be considered a musical synonym for adaptability. As a style, it has influenced numerous musical genres and provided a framework for musical improvisation and communication that has become the standard for musicians seeking to become more flexible and well-rounded in their playing. What can musicians and nonmusicians learn from Jazz? This entry will focus first on a brief history and description of Jazz and present opposing ideologies relevant to the difficulties of defining the musical tradition. It will then break down various aspects of Jazz, explain general practices in learning how to utilize these aspects, and then discuss what is possible for the genre itself and what may be possible for nonmusicians in terms of incorporating Jazz into their own lives.

Keywords

Jazz language · Improvisation · Adaptability · Communication · Flexibility · Multiculturalism · Influence

Definition and History

Etymologically, the word “Jazz” is believed to be derived from the word “Jasm” which is an American English slang term meaning energy or vitality (Lighter 1997). As a musical tradition, Jazz originated in African-American communities in Louisiana, USA in the late nineteenth to early twentieth century. It was the result of the blues, negro spirituals, and ragtime, mixing with European classical and military band music in the multicultural hub of New Orleans.

Stylistically, Jazz is commonly characterized by swing and syncopated rhythms, call and response, and an openness to musicians taking creative liberties during performance.

Jazz bands primarily consist of a “rhythm section” (drums, guitar, bass, piano, or any other instrument capable of providing harmonic or rhythmic structure to a musical performance) and “lead instruments” meant to perform the melody of a Jazz piece (saxophone, trumpet, voice, and any instrument able to produce tones and pitches.) The structure of a Jazz song or “tune, as it will be referred to through this entry, is customarily: The Main Theme (Melody) /an Improvised

Section/Return to Main Theme. Jazz has undergone many different eras and additions, such as Swing, Cool Jazz, Bebop, Hard Bop, Latin Jazz, Jazz fusion, and others with their own specific peak of popularity, roster of well-known musicians, and unique style.

Though we are able to trace the inception of Jazz to a general region, era, and various musical styles, an exact definition of what Jazz is, in some circles, is still heavily debated.

Many musicians have explained Jazz as a feeling. Jazz, in this explanation, becomes a happening; an emotional event that you have to be present for, open to, and ready for when it happens or you won't understand it. The concept of Music as a happening or emotional event is not one unique to this tradition, yet various aspects of Jazz, such as nonverbal/lyrical communication, improvisation, etc., may create a slight barrier of entry for a listener to experience it as such, without previous knowledge or exposure. Some musicians have even stated that the question of what Jazz is, is problematic in itself. In describing this viewpoint, one is reminded of the famous and often repeated quote by legendary Jazz trumpeter Louis Armstrong: "Man, if you have to ask what it [Jazz] is, you'll never know" (Redling 2017, p. 184). While there is nothing inherently wrong with this sentiment and it allows for much freedom within the musical tradition, it does make Jazz more difficult to describe to those interested in learning more about it. Many first-time listeners to Jazz hear the improvised sections of it and cite a difficulty to immediately understand what is happening. When paired with Armstrong's quote, and more like it, it is easy for that first-time listener to interpret their difficulty with the music as a difference in personal taste, rather than an opportunity to learn and enjoy some of the intricacies that distinguish Jazz from other musical traditions.

Another perspective on Jazz seeks to explain it from a traditional scholastic basis. This school of thought tackles the subject of Jazz as something that can be learned from knowing the scales, chords, history, and compositions associated with it. The push for developing a formal and standardized system to learn Jazz comes in direct riposte to the notion that Jazz is all made up, full of

wrong notes, and unrooted in musical theory. On this subject, Famed Jazz musician and Bandleader Wynton Marsalis notes: "Jazz is not just 'Well, man, this is what I feel like playing.' It's a very structured thing that comes down from a tradition and requires a lot of thought and study." (Rinzler 2008, p. 126) While variations of this viewpoint on Jazz have been widely accepted in school curriculum, it has also been criticized, with many Jazz musicians stating that an overly formal study of Jazz leads students to perform without emotion, flexibility, or general musicality.

One of the founding figures in Jazz education, Jerry Coker, states that "Jazz is a very creative, personal sort of music. It is a musical democracy in which diverse approaches abound and are generally accepted. Though there are traditions and common-sense elements, the individual has the relative freedom to express himself/herself at will with respect to the utilization of the tradition." (Coker 1989, p. 14)

Divergent opinions may seem at first to limit the potential and possible for the idiom; in reality, they lead to blended conceptualizations and learning tools for the Jazz listener, scholar, and musician. To explore this blending, it serves to examine aspects of Jazz that are generally accepted as being vital elements of the musical tradition.

Jazz Language

Jazz language can be interpreted as the culmination and development of past, present, and future trends in the performance of Jazz music. To learn Jazz language, players are usually encouraged to transcribe performances of Jazz musicians. To transcribe, one listens to how a Jazz musician plays a tune and analyzes the performance as a whole. A student of Jazz language is tasked with learning how the player tackles both the Melodic and Harmonic substance of their selected musical piece. Students of Jazz are usually encouraged to transcribe improvised solos of a musician who plays that student's primary instrument. The objective is to not only learn the musical notes the musician plays, but to learn how to evoke the

same phrasing and subtle tendencies the studied player has. Phrasing encompasses many different stylistic choices a musician may use to perform a note or musical passage. For instance, A common solo for Jazz saxophonists to transcribe when learning rhythmic phrasing is Sonny Rollins (Tenor Saxophonist) in the tune “St. Thomas” on the album *Saxophone Colossus* (1956). Within this solo, Rollins employs percussive techniques and short notes numerous times and interplays it with strings of notes, before delving deeper into longer note patterns. He also repeats a specific melodic pattern multiple times in various note groupings, which demonstrates to transcribers how one can take a single musical idea and keep it relevant, recognizable, and appealing to the listener, even if it is played in new and different parts of the same song.

Depending on the era of Jazz and/or geographical location the transcription subject was/is playing in, one can find particular tendencies. A Saxophonist playing solo during the Swing Era of the 1920s may sound very different from a Saxophonist playing the same tune in the Bebop Era of the mid 1940s-50s. The Saxophonist from the Swing Era of Jazz may try to create a solo that the audience can dance to, while the bebop saxophonist may choose to create a faster solo and display many complex musical patterns. The effects of transcribing can vary widely. Sometimes a musician may find it appropriate to completely recreate part of a very well-known solo as part of their own during a performance, as an homage. Other times it may be very apparent that a musician has been transcribing multiple performances of a famous Jazz musician, and while they may not be playing a specific solo from that musician, they are emulating techniques and habits of them in their own playing. It is not uncommon for Jazz musicians to compliment and discuss with one another about the influences they heard from each other during their solos. Conversations emerge saying “Have you been listening to a lot x lately? I feel like I heard some similarities in this point of your solo.” For many Jazz musicians, transcribing becomes a rite of passage, a training tool, and way to relate with their fellow bandmate. From a music theory standpoint,

transcribers also are able to see what scales might be appropriate in the performed piece, or what liberties could be taken in the harmony.

Musical phrases and patterns found within the Jazz Language are commonly referred to as “licks”. Licks originate and are discovered in many different circumstances: from sections of standard Jazz tunes, to patterns a famous Jazz musician played in a well-known solo, etc. An example of this is the “Cry Me a River” Lick, which is titled after the song of the same name by Arthur Hamilton (1953). Another example, that has become increasingly prominent in the last 9 years, has been named simply “The Lick.” In 2011, A group of musicians on Facebook and YouTube named “The Lick,” released a found footage compilation video of clips of various musicians playing the same 8 note musical pattern. The musicians in the video were not from the same band, neither had many of them ever met. Many of the musicians in the video spanned several generations, cultural backgrounds and different subgenres of Jazz. This video and more, depicting other musicians playing this pattern in different situations, are now shared frequently among Jazz students. The prevalence of the lick has solidified it as Jazz’s most well-known cliché, or meme. Though there is no consensus on where exactly the lick originated from, this phenomenon demonstrates a unique possibility within Jazz: that two musicians from opposite sides of the world could play a pattern or musical phrase and have learned it from a different source or used it in completely different contexts.

There are also titles for types of licks, such as “2-5-1” licks that are numerous, which denote the patterns’ use in the theoretical harmonic function of the songs they are found in. There exist many books with Jazz patterns/licks notated in sheet music, with usage cases for them. While these are helpful to students of Jazz who are visual learners, many musicians discourage learning these patterns solely through sheet music, as there may be limitations to what can be written concerning the exact specifications of how to use musical phrases in a live situation.

Many musicians learn from each other by using their own ears as guides. Training the ear

to derive information from what is being played, and using this to help in deciding what to perform is a highly valued skill within Jazz. Playing by ear is a skill harnessed through trial and error and developing a wide experience listening to the type of music the listener intends to improvise in. Musicians also learn more about what others are doing in Jazz by attending “Jam sessions” and taking note of what their peers are playing (techniques, patterns, favored tune choices, etc.). Jam sessions are “an often impromptu performance by a group especially of Jazz musicians that is characterized by improvisation.” In this instance, the individual Jazz musician learns from the collective group, and members of the collective learn from the individual. This inter-musician relationship makes growth, experimentation, and commonalities possible within the tradition.

Improvisation

Though licks and other musical information gleaned from the observance of Jazz musicians are regarded highly as tools to learn how to play Jazz, musicians are encouraged to not use them as a crutch or use them all the time in their playing. This stems from the art form’s strong appreciation for dynamic and unpremeditated playing. Examples of this can be found when observing instances of improvisation and musical communication found in Jazz. Improvisation, through the lens of Jazz, is spontaneous musical composition. Improvisation usually occurs after the main thematic material(melody) in a song has been performed, in the form of a solo. During a solo, musicians improvise one after another, either over the entire harmonic form (the chords) of the song, or a specific section of the piece. The underlying harmony is played by the rhythm section. Returning to the example of Sonny Rollins on *St. Thomas*: After the melody finishes, Rollins begins his solo on Tenor Saxophone. He is then followed by a drum solo (Max Roach), and Rollins returns for a second solo at a faster tempo. The pianist (Tommy Flannagan) begins a solo after Rollins finishes, and finally everyone goes back to the “Head” (Melody). Rather than

hard-set rules, there are what should be considered best practices to create a successful solo. One example is that it is advised that while performing a solo, an improviser keeps the original melody within their mind and makes allusions and call-backs to it. This suggestion, while very helpful, has seen many alterations and, in some cases, not been observed in some Jazz solos still considered to be effective by Jazz musicians and musicologists.

In Jazz improvisation, there is great emphasis placed on knowing and highlighting chord tones in a respective piece of music. Chord tones form the basic building blocks of each grouping of notes vital to the harmonic structure of a song. When chord tones are incorporated into a solo, they give the bandmates and the audience of the improviser clues as to where the solo is in the form of the music. If the entirety of an improvised solo does not incorporate any chord tones, it is usually seen as ineffective, as it did not provide any allusion to the most recognizable notes in the harmony of the performed music. Conversely, if a solo only relies on chord tones, it runs the risk of being viewed as boring and ineffective also. One metaphor to chord tones could be the subject or main message of a sentence. In a conversation, if one says a lot of words, but never quite illuminates the subject or point of the sentence, it can give the impression that the speaker is rambling, maybe has forgotten what they were trying to say, or simply had nothing to say. If a speaker merely gives the names of subjects in a discussion, without elaborating, or expositing, that discussion becomes quite dull, leaving the listener with words that lack any connectivity. Soloists are encouraged to find a balance between the two to provide the possibility of understanding and mutual enjoyment to their listener. While this section slightly focuses on music theory and best practices, the goal of improvisation is not to force one to use these concepts and nothing else, but rather provide a framework one can use to create an ad-lib story or conversation. Conversation is a key word here as improvisation, while being primarily focused on the soloist, is also aided by the messages shared between the improviser and band that is performing with them.

Inter-Musician Communication

In Jazz, musicians are emboldened to interact with their fellow bandmates during performance. When communication occurs between performers in Jazz, the piece they are playing becomes less static and more flexible and open to various changes. Communication between Jazz musicians is achieved in a number of ways; there are both visual and musical cues shared between players during performance. For instance, when a soloist is done with their improvised section, and it is time for the band as a whole to return to the melody of the song, the bandleader may tap the top of his head to inform the members of the coming change. This is in reference to the main thematic material of Jazz tunes being termed “The head”. Another tool employed in musical communication is mimicry. Mimicry informs players that not only have they been heard, but that their bandmate will adjust to their playing, and is willing to copy and accentuate the patterns they are performing to aid in their performance. Rhythm and Tempo changes during a solo are also useful for musical communication. In terms of tempo, if a player begins their solo at a very slow pace, this could be a message to the rest of the band to either copy the change in tempo, lower the volume of their own playing, and treat the solo as a ballad. If a player suddenly speeds up in their solo, this could be encouragement for the band to become louder and increase their tempo. For rhythm, there are a number of ways communicative Jazz musicians can change the music, at some points even making the original tune unrecognizable. For instance, if a musician, while playing, decides that they would like to change the rhythmic timing of their solo, they can begin accenting beats that normally would not be as ideal or appropriate in the song. If done intentionally and heard by the rest of the band, the performing group has choices such as changing along with the soloist, or intentionally sticking with what they were playing before to lead into multiple rhythms overlapping; called polyrhythm. Another route a soloist can take while improvising would be to include rhythms more commonly found in other styles of Jazz or genres of music in general. If the

musicians bandmates are also familiar with these rhythms or the type of music associated with them, the group can shift what they are playing stylistically. For example, a slow Jazz waltz could suddenly be transformed into an incredibly fast tune resembling something more akin to Salsa dance music. This is made possible as Jazz students are encouraged to incorporate what they are learning into their own musical style; combining, transforming, and innovating their own influences from other genres of music and personal preferences.

Influences and the Possible in Music Genres

As stated before, Jazz has a long history of melding with and transforming various musical styles both in its inception and development. One example is how, in sharing similar roots as music influenced by the African Diaspora, Samba and Jazz melded together to give rise to Bossa Nova in the late 1950s. Another Instance of this is during the 1960s, when musicians started infusing Jazz into Rock and Roll, Funk, and Rhythm and Blues, resulting in a genre termed Jazz Fusion. This is a very divisive era of Jazz, where many traditionalists refer to the creation of Jazz fusion as the end of Jazz. Other proponents of Jazz argue that Jazz Fusions inception does not signify the end of Jazz, but simply the progress of the musical tradition as it has always been. Jerry Coker surmises that “elements of the Jazz style have permeated nearly all known musical styles and musical functions. Similarly, the open door policy of Jazz has caused the music to absorb and reflect elements of virtually all non-Jazz musical styles, yet retain a sort of diverse identity” (Coker 1989, p. 15).

If a musical tradition’s origin and development is a result of the mixing and melding of various influences, does incorporating another influence signify its end? At the time of writing this article, the Jazz fusion most prominent and popular is Hip hop, Soul, Rnb, and numerous world music genres, all combining with elements of Jazz. The possible for Jazz as a musical tradition is that it is

ever-growing. Jazz will continue to influence, transform, and mix with other genres, and wherever its aspects of language, improvisation, and musical communication are needed, it will show itself.

Conclusion

What can nonmusicians learn from Jazz? How can one embody Jazz or incorporate it into their life? The most obvious answer would be to listen to it; to give Jazz a chance and try to hear what has been described in this article. The reader is encouraged to try and investigate where musical communication is occurring, or listen for influences and language within the solo sections of a tune. The second answer would be to attempt to embody Jazz as a mindset. To embody Jazz as a mindset means to open oneself to respect, gain knowledge from, and embrace the past. It means being able to connect with one another, improvise, and incorporate different influences. The possible for the

nonmusician becomes utilizing aspects of Jazz to adapt to and influence the future.

Leadership

Ryszard Praszquier
Institute for Social Studies, University of Warsaw,
Warszawa, Poland

Abstract

The entry presents a review of definitions of leadership, illustrated by historical development of this concept. It also characterizes various kinds of leadership, from the Great Man theory and early research done at Ohio and Michigan, contemporary ideas such as distributed, shared, authentic, and empowering delineations of leadership.

In doing so, there are introduced mechanisms used by leaders for garnering support, that is, *social influence* and its various manifestations, and *charisma* in its classical personality-based definition, as well as the mission-based one.

The summary section identifies exemplary attempts at measuring leadership effectiveness, concluding that in-depth studies on leadership are still needed to understand this critical aspect of introducing social or business change-making.

Keywords

Social influence · Charisma · Empowerment · Creativity · Social capital

Introduction

Leadership has ancient roots and evolutionary origins that humans have shared with animals for millennia (Van Vugt 2006; King et al. 2009; Van Vugt and Ahuja 2011). Herd leaders help to decide when and where to forage or rest, when to leave a pasturage and how to react to other animals (Van Vugt and Ahuja 2011). Some early definitions of leadership (mainly twentieth century) may be applied to animals as well as to humans, for example, leaders should have an ability to organize participants and direct their attention to issues the leader considers significant (Cyert 1990).

One early delineation of leadership is expressed by tribal societies, such as the Melanesian and Polynesian communities, which evolved into the Big Man paradigm. To become a Big Man took a series of acts that elevated a common citizen to a standing far above his peers and attracted a loyal following (Douglas 1979).

In Hellenistic times, the Roman Emperor Marcus Aurelius (second century AC) supported a similar concept by suggesting, that the leaders should carry themselves with *gravitas*, a Latin word for dignity, impressiveness, seriousness, influence, weight, and presence. Some authors

even today hold that *gravitas* should be a critical quality for contemporary business leaders (Goyder 2014).

Defining Leadership

Interestingly, this model returns in nineteenth century as the Great Man Theory. It describes highly influential heroes who, due to their personal charisma, intelligence, wisdom, or political skills, were able to exercise their power (Carlyle 1988).

One of the earliest definitions of leadership is presented by Bellows (1959), who posits that leadership is creating opportunities for group-members, as to achieve common goals with maximum economy (i.e., minimum of time and work). Similarly, Kouzes and Posner (2008) refer to the group process, adding that the goal to achieve “something extraordinary”: leadership is a process of forming opportunities for people to contribute to making something extraordinary happen.

Early Studies and Ways of Understanding of Leadership

Kurt Lewin’s Leadership Theory

The father of social psychology, Kurt Lewin developed with his colleagues in the 1930s (Lewin et al. 1939) a structure for identifying three basic kinds of leadership that are still mentioned in contemporary sociological studies (e.g., Macionis 2010). These styles are:

- *Autocratic* (directive, authoritarian); characterized by a centralized authority dictating work methods, making unilateral decisions and limiting employees’ participation.
- *Democratic* (participative); characterized by involving team-members in the decision-making process, delegating authority, and using feedback as an opportunity to coach employees.
- *Laissez-faire*; a free-style characterized by giving employees liberty to ask questions, make decisions and complete their work as they see fit. This is probably the most weaker leadership style; however, in some exceptional

therapeutic situations may be effective, for example, the Summerhill school for problem children (Neil 1977).

The Ohio and North Michigan State Universities Studies

In the 1950s and 60s, when the United States experienced its longest uninterrupted period of economic expansion in history, it became important for businesses in the United States to better understand what behaviors make a leader successful. The Ohio and North Michigan State Universities pioneered studies on leadership.

Ohio developed the Leadership Behavior Description Questionnaire (LBDQ, 1800 questions) and its abbreviated version (LBDQ-XII, 150 questions). These questionnaires are still used today (Fleishman 1953; Halpin and Winer 1957; Stodgill et al. 1962).

Their study found two types of behavior to be critical to success:

- *Initiating structure*: a task-oriented behavior, facilitating goal accomplishment (e.g., organizing work, giving structure, defining roles, scheduling)
- *Consideration structure*: a relationship-focused behavior (e.g., building camaraderie, respect, trust)

The Michigan studies added *participative leadership* to the Ohio measures (Likert 1961, 1967).

Contingency Theory of Leadership

Contingency theory holds that situational factors interact with leader’s traits and behavior to influence leadership effectiveness. There are no ideal and fixed leadership qualities. Both task-oriented and relationship-oriented leaders can be effective if their orientation fits the situation. The optimal course of action is contingent (dependent) upon the situation (Fiedler 1967).

The Role of Employees

Situational Leadership Theory

The Situational Leadership Theory (SLT) was developed in the 1970s and early 1980s,

holding that the critical component of leadership is employees' readiness (i.e., competence and commitment) to cooperate. Effective leadership should adjust not only to the task, job, or function that needs to be accomplished but also to the person or group that is being influenced (Blanchard et al. 1985; Hersey et al. 2012).

Path-Goal Theory of Leadership

In the 1960s and 1970s, researchers developed the Path-Goal Theory of Leadership (PGTL), which claimed that the effectiveness of leadership depends not only on the outcomes (performance) but also on subordinates' satisfaction and motivation (House 1971). Based on the conviction that it's critical to maintain an adequate perception of how following a particular *path* will lead to a particular *goal*, PGTL holds that team-members are motivated when they expect that their effort will result in high accomplishments, and that these achievements are rewarded in a valued way (Evans 1970).

Contemporary Approach to Leadership

Transactional Versus Transformational Leadership

Transactional Leadership

Transactional leaders achieve collaboration by exchanging information with followers and by monitoring the performance. They do not take into account the needs of their subordinates. They create an influential ambience, in which individuals are convinced that it's in their own best interest to do as they are told (Northouse 2010).

There are two basic components of transactional leadership (Judge and Piccolo 2004):

- *Contingent reward*, understood as the degree to which the leader sets up constructive transactions or exchanges
- *Management by exception*, defined as the monitoring by the leaders their followers' behavior and taking corrective actions

Transformational Leadership

Transformational leaders (Bono and Judge 2003; Judge and Piccolo 2004; Bass and Riggio 2006) or transforming leaders (e.g., Burns 2003) obtain support by inspiring followers to identify with their vision; they stimulate and inspire followers (Bass and Riggio 2006). It was documented that transformational leaders stimulate organizational creativity (Allen et al. 2013).

The following elements of transformational leadership have been identified (Bass 1985; Judge and Piccolo 2004; Bass and Riggio 2006; Burns 2003; Northouse 2010):

- *Idealized influence*, which basically refers to charisma. Charismatic leaders display conviction. They appeal to followers on an emotional level.
- *Inspirational motivation* is understood as the articulation of a clear, appealing, and inspiring vision. Leaders who use inspirational motivation challenge followers to meet higher standards, communicate optimism about future goal-attainment, and provide meaning for the task at hand (Bass 1985; Judge and Piccolo 2004; Bass and Riggio 2006; Northouse 2010).
- *Intellectual stimulation* inspires followers' creativity by questioning assumptions and challenging the existing status quo.
- *Individual consideration*, which means attending to and supporting the individual needs of followers.

Shared and Distributed Leadership

Shared Leadership is a dynamic, interactive process among individuals and groups with the objective to lead one another. This process often involves peer to peer influence. Leadership is shared, rather than focused on one person (Pearce and Conger 2002; Carson et al. 2007). The team in this approach can be viewed as a potential source of leadership (Mayo et al. 2003).

Distributed Leadership is described as an emergent quality of interacting individuals, repealing the traditional structures of leadership and sharing diverse expertise distributed across many individuals, as opposed to the system of

few acting in a top-down way (Bennett et al. 2003; Bolden 2011).

Leaderful and Teal Organizations

Leaderful Organizations provide a milieu in which everyone participates in leadership. This style challenges the conventional view of leadership through taking co-responsibility and co-leadership; it redefines leadership as a collective practice (Raelin 2003, 2005, 2011).

Teal Organization is advocating for, and enabling, workers' self-management, wholeness, and a deeper sense of purpose (Laloux 2014; Giannobile 2019).

Authentic and Creative Leadership

Authentic leaders acquire their legitimacy through having honest relationship with followers who value their leader's input and see them as open and ethical. By building trust and generating enthusiastic support from their followers, authentic leaders are able to improve individual and team performance (Gardner et al. 2011).

Creative leadership drives change through building an atmosphere prompting creativity, continuously discovering and defining new problems, and implementing the new solutions (Bellows 1959; Basadur 2004). Creative leadership is seen as a core leadership competence (Puccio et al. 2010) and an important way of breaching barriers (Rickards and Moger 2000).

Empowering Leadership

Elaborating on Kouzes and Posner's (Kouzes and Posner 2008) aforementioned definition, a new way to define leadership would be: a process of releasing and augmenting the potentials of groups, communities or societies, leading to taking co-ownership of the idea, pursue it, and make something extraordinary happen.

In lieu of this definition, *Empowering Leadership* is a process that is both value- and efficiency-driven that facilitates the emergence of new occurrences through endogenous dynamics. The process is aimed at triggering the potentials of individuals and groups leading to identifying with, and taking co-ownership of, an idea to make innovation emerge (Praszkier 2015, 2018).

Empowering Leadership has ideas in common with Shared and Distributed leadership, as it instigates co-responsibility, co-leadership, peer-to-peer responsibility, and group-oriented dynamics. It also shares with Creative Leadership the emphasis of augmenting coworkers' creativity, by facilitating and encouraging the bottom-up dynamics of innovating.

A metaphor depicting the empowering leadership style is "Transforming Buffalos into Geese," named after the book "Flight of the Buffalo" (Belasco and Stayer 1993). Buffalo are followers who will do whatever the lead buffalo wants, sometimes even fall off a cliff while following the leader. The book describes two differing types of team leadership.

In the traditional top-down leadership model a leader is responsible for planning, organizing, commanding, coordinating, and controlling the team – an analogue to the "head buffalo herd."

The new approach perceives the team as a flock of geese, flying in unison in a "V" formation, through mutual (horizontal) exchange of information on earth gravity, magnetic directions, etc. Through empowering leadership, "geese" share responsibility for the progress of the entire flock.

Mechanisms Supporting Leadership

To garner support, leaders use such mechanisms as *social influence* and *charisma* for attracting and affecting team members or employees.

Social Influence

At the end of the twentieth century, the understanding of leadership focused on a specific relationship described as "influence" (e.g., Rost 1993); also in the twenty-first-century leadership is seen as an extraordinary influence that is found in a person or a group (Robinson 2010). Leadership may be perceived as a kind of social influence, in which the leader recruits the support and cooperation for the achievement of common goals (Chemers 1997, 2000; Northouse 2010; Kruse 2013).

In an autocratic style of leadership (Lewin et al. 1939) influence is mostly executed through obedience, persuasion, compliance, and manipulation:

Obedience

Several experiments have shown that people tend to obey someone solely because they perceive them to be an authority (Milgram 2009; Martin and Hewstone 2007). People justify their behavior by assigning responsibility to the authority, rather than taking it themselves. Moreover, they might obey orders even when the actions ordered are against their own ethical standards.

Persuasion

Persuasion, on the other hand, is earning subordinates' cooperation through various intentional and non-manipulative efforts aimed at influencing others' beliefs, attitudes, intentions, motivations, or behaviors; as such it differs from exercising top-down authority (Wood 2000; Petty et al. 2003; Gass and Seiter 2013).

Compliance

The use of authority or persuasion may lead to compliance, that is, to adaptation whether or not one agrees with the leader – as long as one's dissenting opinions are kept private. This means adjusting ones' behavior, though not necessarily one's mind. Several studies have documented that greater external pressure generally leads to greater compliance (Freedman and Fraser 1966).

Manipulation

Manipulation is defined as using deceitful influence over subordinates for the leader's own advantage (Braiker 2004; Cialdini and Sagarin 2005; Maxwell 2013). For example, when people are initially persuaded to obey easy commands and, as a result, feel obligated to obey gradually more difficult ones, this kind of manipulation is called entrapment, also known as the foot-in-the-door phenomenon (Freedman and Fraser 1966).

Self-persuasion and Conformity

A more sophisticated method of adaptation is self-persuasion. In this case, people are not forced to follow. Remaining free to choose, they build up internal justifications for obedience. Leaders influence self-persuasion indirectly, by creating situations, where people are prompted to persuade themselves to change their own attitudes or

behavior (Aronson 1999). It involves modifications within the internal cognitive system, rather than external enforcement. This form of adaptation is called conformity, which, as opposed to compliance, involves a change not only in behavior but also in beliefs or thinking, in order to comply with others' requirements (Deutsch and Gerard 1955).

Identification and Internalization

On a higher level of leadership, the earlier mentioned mechanisms of executing authority, that is, obedience, manipulation, compliance, and conformity, would not be satisfactory. Democratic, participative, relationship-oriented, shared, distributed or empowering leadership would gain followers support by earning their *identification* with the leader's vision and objectives. Identification with a leader happens when team-members are influenced by a leader who is liked and respected (Kelman 1958).

Probably the highest level of adaptation or acceptance is internalization, which happens when people adopt a belief or behavior both publicly and privately, without any internal conflict (Kelman 1958). Through internalization people incorporate within themselves new values or attitudes and, in that way, become truly committed and loyal partners in pursuing desirable goals.

Charisma

Personality-Based Charisma

Personality-based charisma, characterized as a compelling attractiveness or charm that can inspire devotion in others, was introduced into the literature by one of the founders of sociology, Max Weber (1978). Charisma, seen as a "magical gift" possessed by leaders, makes their followers strongly identify with the leader (Stark 1997).

This sort of charisma is perceived as a debatable leadership characteristic, being criticized as a "false" leadership trait (Solomon 2014).

Mission-Oriented Charisma

Instead, Praszkiec (2018) proposes Mission-Oriented charisma. "Mission-oriented" means that it is not necessarily personality-based

(as indicated by Weber). Instead, it is a specific radiance power associated with the particular mission, and passion behind its pursuit. Influence is achieved by summoning people to join in a movement for change and in co-leading such a movement (Tucker 1968; Edles and Appelrouth 2014).

Summary and Conclusions

Various definitions and kinds of leadership were presented. However, the field of leadership is dynamic and diverse. Leaders are reaching to various resources, for example, Japanese tradition, applying the Kaizen approach, as well as to modern concepts, for example, Versatile Leadership.

The first, *Kaizen* (meaning “continuous improvement”) refers to various activities that continuously improve all possible functions and involve all employees at all levels (Imai 1986). The Kaizen philosophy and methods spread across the world (Hannam 1993) and are recommended as a contemporary way for enhancing achievements in business (Miller et al. 2013), and beyond, for example, losing weight or quitting smoking (Maurer 2014).

Versatile leaders are capable of flexibly adjusting their leadership style to the people and particular situations. They have a range of methods which they can adapt according to the situation – as opposite to having a single way of leading others (Kaplan and Kaiser 2006). Teams can experience measurable improvements in performance when becoming versatile, that is, when people learn to adapt to others’ social styles (Leimbach 2009).

The contemporary approach to leadership, for example, the empowering leadership, seems positioning creativity as a central mechanism for achieving challenging goals. Creativity is here seen as a reflective, but also playful dialogue between diverse perspectives: “creative actions (...) open up, exploit and expand the possible” (Glăveanu 2018, p. 527).

There are also attempts to measure leadership effectiveness, especially whether the style of leadership affects the organization’s outcomes

(Madanchian et al. 2017). For example, there is a method for assessing leadership effectiveness (“Essential Behavioral Leadership Qualities,” Oyinlade 2006). There is also an interest in identifying leaders’ personality traits (e.g., Hogan et al. 1994), especially in cross-cultural context (e.g., Silverthorne 2001). Moreover, studies indicate that influence moves in both directions: the characteristics of group members are also influencing the leadership style (Sogunro 1999). It seems however, that studies on leadership effectiveness are still an open-end issue, prompting scholars for more in-depth research.

Liminality

Bem Le Hunte
University of Technology Sydney, Sydney, NSW,
Australia

Abstract

The contemporary concept of “liminality” comes from the Latin word for “threshold” (limen or limin). Coined first by the folklorist, Arnold van Gennep, the liminal was defined as a moment of transition in the status of an individual in a ritual context. Van Gennep noted that in cultures around the world rituals could be divided into three stages – a before and after – with the liminal state in the middle, when mapped on a timeline. For example, there were preliminal rites (or separation rites), when an initiate was separated from the old and routine world, and postliminal rites, when an initiate

could be reincorporated into society. The in-between period formed the marginal or liminal phase, marked by liminal rites, where identity could be deconstructed, disoriented, and reformed, so that the initiate could be returned to society with a fresh identity and status. Van Gennep wrote that the concept of liminality could be seen as universal, and that the markers of liminality accompanied transitions of status, place, and time. (For example, a marriage can be seen as a transition between different states, movement away from home is a transition between places, and New Year rites are a transition between different moments in time) (Van Gennep 1909). Victor Turner revisited Van Gennep's notion of liminality in the context of male initiations in the Ndembu, and described the liminal phase of a male initiation ritual as a state "betwixt and between" – that interstitial no place, no time when the initiand is neither boy nor man. This time of ambiguity, disorientation, and disruption served to dissolve identity and disrupt the very structure of society before returning the initiate to the new state. Turner described the liminal society created for initiands as a "communitas" – a world that was utopian in nature – where initiands were treated as androgynous, seen to be occupying another place and marked by a sacred poverty and fraternity (Turner 1967).

This entry explores how the concept of liminality can be interpreted through the lens of possibility studies, as a fertile, emergent, and powerful stage where ordinary life or social states are disrupted – periods of time where transformation and transition can take place.

Introduction

The idea of change and transition is integral to the notion of liminality – and this transitory phase be

seen from an individual or social perspective. In this way, liminality is a process of becoming – a state of flux and change where the old self or the old rules and ways of being in society are reinvented in preparation for new ways of being, thinking, living, behaving, and organizing. The idea of the liminal gives us a powerful framework for many themes in possibility studies. Futures thinking and forecasting assume a stage of liminality or "becoming" – a state between the present and a desirable future world. Similarly, the study of utopias becomes the exploration of a society in a liminal state or "communitas." And even the study of creativity involves a state of "becoming" through engagement with a phase of emergence and not knowing. These social states and individual acts have creativity and transformation at the core, and their transformations follow the patterns of transition identified by Van Gennep and Turner, as they all take place over time and space with a time or stage that is "betwixt and between" for the emergence of the new.

Liminality in Myths and Stories of Transformation

While Van Gennep and Turner focused on liminality and ritual, Joseph Campbell looked at the role of liminality in myth and story. Campbell claimed that the heroes in myths around the world followed the three same phases of transition and transformation. A hero had to leave the comforts of their world to enter a liminal world and answer a "call to adventure," rich with possibilities, even stepping through a threshold (or "limin"), often as a reluctant hero, requiring a guide or mentor to help them enter the liminal phase of transformation. Having stepped over this threshold, the mythic world then opens up for the hero, where they have to slay demons and overcome deep fears within themselves. The liminal makes it possible for the hero to discover their own power – to discover the possible – as they face the unknown (represented by monsters and other such mythic challenges). Once they have undergone these challenges they win a boon, together with a sense of self-realization or atonement

(think at-one-ment), after which they are able to return to their world with a gift (not dissimilar to the Ndembe initiate returning to a new world with the status of a man). Campbell saw the hero's journey mirrored in the challenges of human existence when facing unknowns. Important in the phase of flux is the transition from the individual state of being to this state of atonement with Being – the source of all life (Campbell 1993).

This idea of leaving behind the world as we know it, entering and exploring a liminal world as a site for the possible, and returning to a renewed life and world enriched with a higher purpose, not only plays into the themes of possibility studies (futures, social, and individual transformation), it also mimics the three-act structure of Van Gennep's – and indeed has helped inspire many three-act structures in thousands of films, from Hollywood and beyond (Vogler 2007). With ideas of liminality so closely woven to notions of exploration, discovery, (and self-discovery) and the unknown, they unveil a curious dimension (and questions) around how to enable and amplify the "possible" by purposefully entering liminal times and states to catalyze new forms of understanding. Campbell's work also helps us understand transformative cognition, which supports the idea that transformative experiences make profoundly significant changes to core beliefs possible, and change what we know and value about the world.

Liminality, Utopias, and the Possible

Possibility studies is inherently rich with potential – opening up a kind of "possibillionism" as it relates to so many fields. Exploring the possible allows us to examine what could be, what is to come, what might have been, and what is not or might never be (Glaveanu 2021). While Glaveanu's taxonomy of possibilities explores expressions of "being," the idea of "becoming" is inherently linked, and the liminal provides the conditions and context – the time and space continuum – for things to "become" possible.

Models of liminality serve to help us understand societies in transition, where old ways are

being rejected and the new have yet to arrive. This social experimentation with the possible is the work undertaken by utopian societies that experiment with speeding up this transition by creating a liminal society or "ideological communitas" devoted to exploring future possibilities. The word "utopia" was first coined by Sir Thomas More in 1516 with the notion of liminality embedded – as the word utopia came from the Greek word *ou-topos* or "no-place" as well as *eu-topos* or "good place." It was a good place, yet it did not exist, except as a liminal concept. Others have theorized utopias as a place that are "betwixt and between" to use Turner's phrase, and there is a strong sense that they perform the labor of "the possible" by experimenting with multiple perspectives and ways of living in the phase between worlds. Many scholars have identified the utopian society as a group of people who organize their life around shared purposes and are to some extent **separated from the world or mainstream society** (Sargisson and Sargent 2017). In order to conduct the experiment in a future society they are required to occupy a liminal space, much like the Ndembe initiands who took on new ways of being. There are an increasing number of such experiments into the possible. From the nineteenth-century utopian societies through the hippie communes of the 1960s – right through to the third wave of around 10,000 ecovillages spread over 144 countries (Global Ecovillage Network 2021).

Historically, societies have experienced times of relative stability, followed by a period of transition to a new way of organizing, thinking, and being. This is evident in many ways – the Industrial Revolution – or the transition from nomadic to agricultural society. Or the emergence of the Age of Enlightenment. Or even the transition from nomadic to agricultural society. The time "betwixt and between" when society experiments with new possibilities can be seen as a time of liminality. There is flux and uncertainty and disruption as society rethinks its ideals (for example, about whether slavery is appropriate), reorganizes its structures (for example, through the land reforms and Enclosure Acts that contributed to urbanization in England in the 1700s), or reimagines its

technologies (think the emergence of the Internet). All of these liminal phases provoke an intense focus on “the possible,” where people are forced to explore the generative capacity that the liminal phase affords – before new rules and structures and ways of being arrive. Transition studies aim to understand some of these structural changes that are taking place in our world currently, and consider the profound changes that every one of our systems will have to endure if we effectively transition to a sustainable future. Current utopian societies also attempt to create an “ideological *communitas*” for new ways to live. Karen Litfin tries to convey the brave experiment that a utopian society represents in this process of transition, likening ecovillages, and intentional communities to pioneer weeds that reach out into the sands of the deserts we have created – the liminal spaces left destroyed – in an attempt to fertilize the soil for new possibilities. “Typically, the pioneer species are not the most glamorous of plants – think thistle – but their restorative work is absolutely essential. . . . Like pioneer species, ecovillages are preparing the ground for a viable future and we can all learn from their experiments” (Litfin 2014).

Liminality, Learning, and Unlearning

Van Gennep, Turner, and Campbell all wrote about how our society, stories, and culture enable personal transitions and help initiands and heroes navigate unknowns (through mentorship, rituals, social structures, and mindsets.) Liminality and thresholds have been explored in education as a way to understand how learners (think initiands) transform from those who do not know to those who are capable of becoming mentors themselves. In a learning journey there is often a liminal time when knowledge becomes “troublesome.” This encounter with knowledge “renders things fluid, less certain than they used to be, and starts to transform the learner.” It “often feels like a space where you are losing things. . . . it is a space where you have to let go of your prevailing way of seeing, your prior understanding, and your prior schema. That has to weaken or loosen, or be

transformed, in order to gain a newer way of seeing, or newer mode of being.” Letting go of the old way of knowing is hard as “we don’t like letting go of things that we think we have a very good handle on, or that we have become reasonably good at” (Land et al. 2014).

While mentors (wonderful teachers) are important to help initiands and students to do this work, structures are also important. “Third spaces” in education where structural boundaries merge can be disturbing as well as inspiring. For example, a liminal space is created where education transcends institutional boundaries or brings people together with roles beyond the distinctive separation of academic, industry partner, student, or professional staff – instead privileging a flatter hierarchy and mutual learning. Education can also be “a conceptual space” where disciplines come together through transdisciplinary learning exploring “the liminality between epistemologies and ontologies, disciplines and individuals” (Kligyte et al. 2019). Online work in a pandemic serves as another liminal space, as does a virtual internship, or the transdisciplinary liminality when disciplines converge. A kind of in-betweenness emerges, which imbibes these third spaces of learning with qualities of “radical openness” (Soja and Hooper 1993).

As learning through threshold concepts and liminal spaces is infused with qualities of “becoming,” it is important to consider the role of creativity in learning, as creativity is inherently a liminal process. The creative process has all the markers of a liminal experience in the sense that it allows the practitioner to spend time away from the time and space continuum of the ordinary world and ordinary ways of thinking – like the Ndembu initiand. Many writers, for example, speak of a creative process “where their surroundings disappear” (Le Hunte 2010). Stephen Nachmanovitch wrote that all creativity is a form of improvisation, also known as extemporization, meaning both “outside of time” and “from the time.” He believed that “in improvisation, there is only one time” (Nachmanovitch 1990). Csikszentmihalyi calls this state an “extended present.” American poet Mark Strand describes the experience of being in this state as follows:

Well, you're right in the work, you lose your sense of time, you're completely enraptured. . . The idea is to be so so saturated with it that there's no future or past, it's just an extended present in which you're, uh, making meaning. And dismantling meaning, and remaking it. Without undue regard for the words you're using. It's meaning carried to a high order. (Csikszentmihalyi 1996)

The synchronic time that becomes available in this liminal phase of illumination is rich with the generative, serendipitous potential of the possible (Le Hunte 2021).

Conclusion

Traditionally, liminality can be described as a state of flux and discovery – a state of “becoming” – situated between two phases of relative stability. Through this lens, liminality is a moment of transition and transformation – a time and place out of ordinary time or space to negotiate a new stage in life (as explored by Van Gennep and Turner). Liminality can be identified as the middle stage of a challenging learning journey (through the educational lens of threshold concepts and troublesome knowledge). It can also refer to the stage of disruption or experimentation between different stages in societal evolution, as exemplified by the practice of utopian thinking and utopian societies. And it can be seen as a phase between different stages of consciousness (when seen through the transformative journey of the hero).

The notion of liminality was first explored through the work of Van Gennep and Turner as the middle phase in ritual when an initiand is taken from an old world and reinstated in a new one. While the phases in ritual are stylized and structured in these traditional rites of passage and in myths around the world, there is an understanding that any individual who has gone through the liminal phase and come through the other end has traversed a path of some sort of transformation – from a state of not knowing, to knowing, from someone who operates as an individual to someone who operates for the

collective (and even brings a gift to that collective) (Campbell 1993).

Moving beyond traditional societies where the notion of the liminal was first explored, the idea of this interstitial state “betwixt and between” is still relevant. As the flux of personal and social change accelerates well beyond that experienced historically, and as we career toward futures that are more supercomplex and unknowable than previously (Barnett 2012), liminality is amplified and sustained for longer periods of time. In the context of a society in rapid transition, navigating the accompanying unknowns becomes an urgent imperative. As such, the exploration of the inherent creative potential of liminal spaces, as sites to explore “the possible,” becomes a crucial way to invoke individual and social transformation.

Malevolent Creativity

Mark A. Runco

Keywords

Malevolence · Benevolence · Creativity ·
Divergent thinking · Dark side

One key question in this *Encyclopedia of the Possible* is “what is possible,” the underlying interest being, “what might occur in the future?” Some answers to this question are highly optimistic. They may even imply that some sort of utopia is possible. After all, if humanity learns from its mistakes and evolves in the right direction, eventually good will prevail and bad may disappear.

Is utopia possible? Would utopia really be a good thing? It is possible that there is a need for both good and bad in society. This view is suggested by the fact that in some ways humans require contrasts. This is certainly true on a neurochemical level and on a perceptual level (e.g., the receptors in the visual system). It is also too often true cognitively; we sometimes appreciate the good only when we see or experience the alternative. This may be why the definition of utopia usually begins with the word “imaginary,” as in “utopia is an imaginary place filled with good and lacking all bad.” The original description of utopia seems to have been a book by Thomas More, published in Latin in 1516. It is

usually described as a satire, so More himself very likely questioned the possibility of utopia.

Even if utopia itself is impossible or less than completely desirable, society can move in the direction of good. This would involve the reduction or elimination of crime and corruption. Even more broadly, society would be improved by a reduction of malevolence. There remains the question of feasibility. That is because malevolence can be creative, which means it adapts and evolves and finds novel ways to express itself.

This chapter focuses on the questions surrounding malevolence. It summarizes current thinking about malevolent creativity and examines implications for the question of “what is possible.” It begins with some key definitions and a discussion of the history for the concept of malevolent creativity.

Creativity in the Moral Domain

Malevolent creativity has been recognized for quite some time, but it became what might be considered a coherent subfield in about 1993. That is when Howard Gruber and Doris Wallace edited a special issue of the *Creativity Research Journal*, the focus of which was “creativity in the moral domain.” True, there were occasional discussions of immoral creativity before 1993. The best known is that of Rogers (1959) who is famous for his work on self-actualization and

creativity but also recognized “bad creativity.” He wrote:

My definition of the creative process is that it is the emergence in action of a novel relational product, growing out of the uniqueness of the individual on the one hand, and the materials, events, people, or circumstances of his [or her] life on the other. . . It makes no distinction between “good” and “bad” creativity. One man [person] may be discovering a way of relieving pain, whereas another is devising a new and more subtle form of torture for political prisoners. Both these actions seem to me creative, even though their social value is very different. . . Galileo and Copernicus made creative discoveries which in their own day were evaluated as blasphemous and wicked, and in our day as basic and constructive. (Rogers 1959, p. 71, brackets added, italics in original)

Leonardo Di Vinci could be mentioned here, given that he designed so many weapons and instruments of war (Runco 2007). They were highly creative and designed to harm or even kill.

Not all malevolent creativity is intended to harm. Consider, for example, Spooner’s (2006, 2008) research on graffiti. As Spooner demonstrated, graffiti is often creative and usually illegal. It may damage public infrastructure, at least in a superficial way. Graffiti is not always considered to be malevolent or illegal. Spooner explained the different interpretations of graffiti by emphasizing attitudes. He quoted Agnew (1989) who described how *Zeitgeist* influenced views of bad creativity:

These early views [e.g., Rogers 1959] were eventually rejected or forgotten, not so much because of the accumulation of evidence against them—but more because certain social changes in post-World War II America lead researchers to focus on the positive aspects of creativity. The research evidence, however, suggests that there may be some validity to the early assertions linking creativity and crime and delinquency. (p. 104)

Thus, contextual factors must be acknowledged, especially when thinking about emphases in research (good or bad creativity). And not only did concerns about good or bad creativity change with the times, so too did the science of creativity. Put briefly, the world kept changing, problems became more pressing (e.g., climate crises, medical dilemmæ), and fortunately studies of creativity became more and more scientific. This has allowed objective study of good and bad creativity.

The special issue of the *Creativity Research Journal* mentioned above was titled “creativity in the moral domain.” Its contents are varied, and quite a few of the articles in the 1993 special issue mentioned the antithesis of moral creativity. Some of these referred to immortal creativity, but Robert McLaren (1993) had a different label. He called it “the dark side of creativity.” That label really caught on.

Various case studies were included in the 1993 special issue. One covered individuals known as “rescuers,” their moral creativity being expressed in actions that saved others. This article went into detail about Oskar Schindler, the German businessman whose creative efforts saved a large number of Jews from the Nazis. Other articles in the special issue discussed things like nuclear weapons and computer viruses. Note, then, that there was work on creative people doing moral or immoral things but also work on the results of the creative process.

Creative Products

The creativity research is often separated into work on creative people, the creative process, creative potential, persuasion, creative places, and creative products. The last of these areas is especially interesting because products can often be used in more than one way. Nuclear weapons were possible because there was research on nuclear energy, for example, and computer viruses are possible because of software development and because the Internet is now just about everywhere. The point is that there are sometimes clear benefits to discoveries and inventions, but when taken in an immoral direction, there are also dangers. One creative product can sometimes be used in moral or immoral ways. Is a product that has both beneficial and harmful applications malevolent? The only way to know is to look at the intentions. Why was it created? More will be said about intentions below.

First, it may be useful to summarize my own contribution to that 1993 special issue:

Stephen Carrie Blumberg, a small, wiry, dark-haired man, was convicted in 1991 of stealing books. His was a noteworthy conviction because

he did not just abscond paperbound romances from convenient bookstores. Over a 16-year period, Mr. Blumberg stole in excess of 24,000 volumes—an estimated 19 tons of books from 48 U.S. States and throughout Canada. The value of these books was estimated to be between \$2 and \$20 million. One of the books Blumberg stole from my alma mater-Honnold Library of the Claremont Colleges—and is worth an estimated \$35,000. It is one of few histories of the world which does not include any discussion of Columbus. It was written in the year 1493... Blumberg is a master of breaking and entering the rare book rooms of libraries. He... knew how to pick locks, fake identification cards... and thwart electronic security systems. He was adept at scaling rooftops and dumbwaiters to gain access to hidden collections. One associate described the 130-pound, 5-foot-9 man as ‘Spiderman’... When the FBI raided Blumberg’s home, they found books everywhere—and 50,000 antique brass doorknobs. He had a passion for books and antique doorknobs. Blumberg is a talented individual, but clearly his talent gone astray. Too bad he is not more like the superhero Spiderman and ‘a good guy.’ But for that matter, it is also too bad that Hitler did not use his skills of persuasion to socially beneficial ends. There are many examples of persons with great talent but immoral or otherwise undesirable tendencies. Indeed, one argument in the present article is that creative talent and morality are largely independent. (p. 17)

At about the same time as the publication of the special issue of the CRJ, devoted to creativity in the moral domains, Gardner, Csikszentmihalyi, and Damon published an interesting volume on *humane creativity*. This is a different label for moral or benevolent creativity. That volume (and the subsequent volume by the same authors from 2008) also indicated that the interest in creativity and morality (and malevolent creativity) grew. Not surprisingly, increasingly rigorous methods were brought to bear on the topic. Indeed, psychometrically sound measures were developed that focused on malevolent creativity. Some of these estimate both benevolent and malevolent creativity, but several focus on the latter.

As a matter of fact, this is one curious trend that can be seen if you stand back from the research and consider what has been published since McLaren’s article (1993) on the dark side. More and more articles focused on the dark side and fewer and fewer on moral creativity. There was,

for example, research on the creativity of criminals (Brower 1999; Eisenman 2008) and various investigations of the particular personality traits – the so-called dark triad – underlying malevolent creativity. That dark triad of traits includes psychopathy, narcissism, and Machiavellianism. Just to summarize one investigation, Kapoor (2015) assessed each of these and a composite of them, as well as several measures of creativity, to a small group of Indian adults. He reported that indicators of positive creativity were correlated with narcissism, while negative creativity was correlated with psychopathy. Lee and Dow (2011) also reported relationships between personality and malevolent creativity.

It is no surprise that personality has been tied to benevolent and malevolent creativity. What may come as a surprise is that even though the initial interest was in creativity in the moral domain (Gruber and Wallace 1993) and humane creativity (Gardner et al. 2008), for at least 20 years now, more research has been focused on immoral creativity and the dark side than on moral creativity. This may not be all that much of a surprise when you consider that malevolence is generally more salient than morality and benevolence. Just look at television: how many crime shows are on the air? Look at the news, where human interest stories are far outnumbered by the more sensational crimes and crises. Humans have an inborn tendency to attend to salient information, and malevolence is by and large more salient than benevolence. This may partly explain why more research has been done on malevolent creativity than on benevolent creativity. Or perhaps it is just that malevolence often reflects something that should be eliminated, a problem that must be solved.

It is easy to offer additional examples of the broad interest in malevolence. Dow (2015) investigated *cryptomnesia*, a form of plagiarism, as related to performance on various creative tasks. She found that individuals with limited knowledge – simply put, novices – were more likely to suffer from cryptomnesia than more experienced individuals. Cognitive load played a role (i.e., how much information was being processed at any one time) as well. Interestingly, Dow did not rely on the written word but had visual and

auditory tasks and stimuli as well as verbal. When a design task was used with novice and expert engineers, the presentation of an example had an impact, but only for the less experienced participants.

Cryptomnesia was defined by Dow (2015) as inadvertent plagiarism. If plagiarism is advertent, it is immoral; but if it is inadvertent – and thus satisfied the definition of cryptomnesia – it is not immoral. It could be an accident, but in any case the individual was not trying to cheat. Recall here what was said above about the role of intentions.

There are other clear examples of creativity used intentionally to harm or for personal gain. Cropley and Cropley (2011, p. 313) explored *lawbreaking*:

some lawbreaking involves generation of highly effective—even admirable—novelty, and some lawbreakers display psychological characteristics typically associated with creative individuals, so that a deficit model is inappropriate. Creative lawbreakers and law enforcers can be conceptualized as competitors in much the same way as businesses are competitors, and this suggests a fresh way of looking at law enforcement.

Yet another variety of intentional and malevolent creativity is apparent daily, in the USA, since 2016. That is when a very different administration was installed in Washington DC and “for-profit politics” became the norm. Certainly politics has always had a creative streak, well before 2016. An obvious example of this is “spin,” where the most euphemistic message possible in what might seem to be bad news is shared with the public, the spin being a creative interpretation of the facts. But since 2016 the Washington Administration has taken this to new heights. Detailed discussions of this political creative malevolence have been presented by Runco (2017, 2019) and Sternberg (2017).

Empirical work in this general direction was reported by de Saint Laurent, Glaveanu, and Chaudet (2020). They examined verbal products for creativity and malevolence, but unlike previous research, their focus was on tweets. de Saint Laurent et al. were particularly interested in the anti-immigration content of tweets. Anti-immigration has been one of the foci of the current administration in Washington DC, and quite

clearly the efforts are contrary to laws allowing asylum and legal immigration. de Saint Laurent et al. used an innovative method; they examined:

112,789 anti- and pro-immigration tweets, having identified target tweets based on specific hashtags. Interestingly, analyses indicated that malevolence in tweets is quite distinctive and those posting these tweets ‘employ a series of specific strategies in creating echo chambers online’. (p. 66)

An example strategy uses new slogan and word variations that signal the group identity of the individual posting the tweet and thus build community within the anti-immigration segment of the population. Given the popularity of Twitter, more research should be considered. The methodology is impressive. Just look at the data set: 112,789 tweets.

Measures of Malevolent Creativity

Other new and innovative methods have been developed to empirically study malevolent and benevolent creativity. Here again, it appears that there is more interest in the former than the latter.

At this point there is no shortage of measurement options. A handful of studies have used some form of divergent thinking to get at the dark side and negative creativity, while others, mentioned above, have used some sort of personality assessment (usually targeting the Dark Triad).

The *Malevolent Creativity Behavior Scale, MCBS* (2016) was developed to measure ideas about malevolence rather than the relevant personality traits. It is an extension of an existing measure of ideational behavior (Runco et al. 2000). The original measure was developed as a criterion for divergent thinking tests, outside of the context of malevolent creativity. Divergent thinking tests are open-ended and ask examinees to generate ideas, options, and alternatives. They often encourage examinees to be original. The tests provide scores for fluency (how many ideas a person produces when solving a presented problem), originality (how many statistically rare ideas that person produces), and flexibility (how many conceptual categories are used in all ideas

produced). Divergent thinking tests are probably the most commonly used measure of creative potential (see a recent review by Runco and Acar 2019), though they are certainly measures of potential. Just because a person does well on a divergent thinking test – or any test purporting to assess creativity – there is no guarantee that the person will in fact be creative when outside of the testing setting.

Divergent thinking tests do have adequate predictive validity, but most investigations of this predictive validity have used dubious criteria – criteria that may focus on creative behaviors which may have little if anything to do with ideation. For this reason, Runco et al. (2000) developed the *Runco Ideational Behavior Scale* (RIBS). It only asks about ideas, not attitudes, traits, or other correlates of creativity, and sure enough, when used as a criterion with tests of divergent thinking, it supports the predictive validity.

It was worth going into some detail about divergent thinking because it is related to the question found in the first paragraph of the present article, namely, “what is possible?” There is an entry in this same *Encyclopedia* that is focused on divergent thinking precisely because it allows people to explore all directions of thought, and this is quite helpful when considering what is possible. As a matter of fact, divergent thinking is most likely to lead to a creative idea when it can go in all possible directions. In other words, people are likely to be most creative if they do not just think about solutions and ideas in one direction but instead consider ideas in what may be a conceptually the opposite direction! Recall here what was said early on in this article about the possibility that utopia is not all good but instead requires antitheses. Divergent thinking allows people to consider antitheses, including options that indicate “what is possible.”

One last point about the Malevolent Creativity Behavior Scale. Its focus is on ideation, but note the “behavior” in its name. That is in the name because the measure also focuses on manifest action. It is not about feelings, or attitudes, or other things that must be inferred from what is observable. The MCBS asks only about observable actions. Admittedly it is a self-report, and

care must be taken with all self-reports because of the potential impact of memory, honesty, and socially desirable responding.

One analysis of the MCBS with a sample of just under 1000 individuals suggested that there are three distinct scales: ideas about hurting people, ideas about lies, and ideas about playing tricks on people. Very importantly, MCBS scores predicted individuals’ malevolent creativity performances as assessed with realistic, open-ended problems.

Kapoor (2015) developed another self-report that estimated the likelihood that the individual would use creativity in a negative fashion. Situations are given on his measure, and respondents use a Likert scale to indicate how likely they are to emit certain behaviors. These are indicative of positive creativity, negative creativity, or neutral (no creativity). Interestingly, the reliability of the negatively creative items was the highest of the three subscales. Recall what was said above about potential problems with self-reports (also see Kapoor and Khan 2016).

One last study fits under the measurement heading and must be summarized because of its implications. This is an investigation using the Alternative Uses divergent thinking test. Dumas and Strickland (2018) examined responses to Alternative Uses and developed a scoring system that identified malevolent ideas (e.g., hitting someone over the head with a book as a “use for a book”). Dumas and Strickland reported that males were significantly more likely than females to be malevolent, at least on these particular tasks, and respondents who were more original were also more malevolent than those who were less original. This finding is consistent with the idea, introduced above, that malevolence is indicative of a general sort of divergence of thought. As a matter of fact the malevolence of the respondents in the Dumas and Strickland investigation could be predicted from the level of originality of the individual giving the ideas.

Conclusions

This chapter focused on malevolent creativity but started with a discussion of the opposite, namely,

benevolent creativity, or what was early on called creativity in the moral domain. Importantly, that early research uncovered what may be the key element, namely, *intentionality*. Both Gruber (1993) and Runco (1993) argued that intentions must be taken into account whenever creative morality is discussed. Intentions are also key when there is an interest in separating benevolent from malevolent creativity, as well as negative creativity. Simplifying slightly, some creativity is harmful, but not intentionally so. The creator may have been focusing on an original product and the malevolent application a by-product. Other times the harm is attributed by an audience but was not part of the creative process used by the creator, in which case the creative effort was not malevolent. This is better called *negative creativity* (Clark and James 1999). The examples mentioned earlier, where work on nuclear energy also led to nuclear weapons, would fit here in that the original intent was to benefit humankind rather than bomb it.

A small point about the vernacular. First, the label intention is not always used in the research. Cropley, Cropley, Kaufman, and Runco (2010), for example, defined malevolent creativity using a different term. They referred to the *deliberate* use of creativity to harm others. Second, there are different perspectives on benevolent or moral creativity as well as different labels. Furnham (2015) suggested that there is a *bright side* as well as a dark side to creativity. He supported this idea with an investigation using both personality measures and a test of divergent thinking. Unlike most other research, he sampled managers – over 4000 of them. Importantly, his analyses confirmed that the dark triad of personality traits offered information that is not found in broader batteries used to assess personality (e.g., the Big Five, which measures openness, neuroticism, extraversion, agreeableness, and conscientiousness). Openness seemed to be most important for the bright side of creativity.

Are there really dark and bright sides? A few years ago I wrote a chapter titled “creativity has no dark side.” The thesis was that there is one creative process and that it allows individuals to construct original and effective solutions and ideas. These solutions and ideas might be

benevolent or malevolent, but the process is the same – and value-free. The difference between benevolent and malevolent creativity, in this theory, is in how values direct the process (through intentions). Someone who values harmony and cooperation, for example, is likely to use his or her creative capacity to find original and effective methods for socially useful solutions. Values can be separated from the creative capacity, however, which is what led to the conclusion that creativity has no dark side. Creativity is the process that leads to original and effective ideas, and it may be directed one way (benevolence) or another (malevolence).

The view that “creativity has no dark side” is one of various perspectives. Another is that creativity merely occurs and that much of what is labeled “dark,” malevolent, or deviant is a reflection of the attributions by some audience and not inherent in the work itself (Runco 1995; Spooner 2008). As Spooner put it:

creativity may be channeled through various avenues and applications and, by its very nature, it will, at times, be judged as either socially acceptable or nonacceptable. (p. 129)

The phrase “at times” is a reminder about one point made earlier, namely, that context and Zeitgeist are relevant to definitions and judgments of malevolence.

Now we can turn back to the provocative question that opened this chapter, namely, that it is possible that malevolence may be necessary. It may be unavoidable because some of it is creative and adapts, but it is also possible that even a utopia requires the interplay of benevolence and malevolence. That being said, society is at present no where near a desirable balance. There are wars, starvation, injustice, bigotry, and crime all over the globe. It is even possible that society is moving farther and farther away from utopia. Society is in many ways moving deeper and deeper into trouble. At the same time, there are many reasons to celebrate. Life expectancy is increasing, for example, and many diseases are being cured or even eradicated.

This may be explained by the fact that malevolence may be a natural and even necessary feature of society. It certainly is necessary if we want

creativity and innovation. As mentioned above, creativity requires consideration of a wide range of options. If the process is constrained such that only certain kinds (e.g., moral) of ideas are considered, there will not be as much creativity because thinking will not be as divergent. If you allow it to be divergent, there will be a wider range of options and more creativity, but some of the ideas will be malevolent and some benevolent.

The Matrix of Maybe

Roy F. Baumeister¹, Heather M. Maranges² and Hallgeir Sjøstad³

³Norwegian School of Economics, Bergen, Norway

Abstract

The matrix of maybe can be defined as a way of conceptualizing the future, either imminent or distant, as a set of options, only some of which will come true. The “maybe” is meant to invoke not only the options readily available but also the uncertain nature of their consequences. For example, people may choose a job or a spouse from among several options, but making the decision brings a new set of possibilities (*maybes*). The selected job or spouse could in turn lead in various different directions.

Keywords

Possibilities · Multiple possibilities · Decision · Choice · Future · Prospection

Synonyms Multimaybe matrix (*see Matrix of Maybe*)

Introduction

The notion of a “matrix of maybe” (or multimaybe matrix) emerged from research and theory regarding how people think about the future. It encapsulates a view of the future as containing multiple alternative possibilities, indeed multiple *sets* of alternative possibilities.

There are two main competing theories about the future. The tension between them can be seen both in the everyday actions, thoughts, and feelings of ordinary people and in high-level theoretical disputes among experts. One of them views the future as a single path, and what happens is largely or even strictly inevitable. The alternative is the matrix of maybe, in which the pathways into the future have many forks at which things could go in different directions.

Although the indeterminate nature of the future may seem intuitively obvious, it has been disputed throughout history by various assertions of the single-path view. Fortune-tellers and prophets from ancient times asserted that the future could be known in advance. Religious views of predestination invoked divine omniscience to deduce that the future is already determined. Even scientists and philosophers have argued that the laws of nature leave nothing to chance, and so everything that happens is inevitable (*see Determinism entry*).

Meanwhile, the multimaybe view of the future also has distinguished intellectual precedent. Decision-making theory and classical probability theory assume that the same present is compatible with multiple possible future outcomes. Existential philosophy developed the concept of an “ontological horizon,” which means all the future outcomes that can be reached from one’s present point in space and time (e.g., Heidegger, 1927). Social psychology, a field that studies situational influences on human behavior, has often studied aspects of situations that are defined by multiple possibilities, such as threat, opportunity, having an escape option, varying amounts of freedom and

choice, competition, cooperation, contingencies, responsibility, and power relations. That is, both social psychology and decision research typically presume that humans are capable of making choices among competing alternatives.

The ability to imagine the future as containing multiple alternative possibilities is a recent evolutionary innovation and may be unique to humans. An experiment by Redshaw and Suddendorf (2016) offered a convincing test of this idea by using a vertical tube that had two openings at the bottom, left and right. Treats were dropped into the top and came out the bottom whereupon they fell into a hole and were lost unless caught by hand. To be sure of catching the treat (rather than just getting it half the time, based on guessing), one had to use both hands, one for each opening. Human 2-year-old children could not master this, but the 3- and 4-year-olds quickly mastered the task and got the treat every time. In contrast, adult chimpanzees, gorillas, and orangutans never figured it out. They continued to guess with one hand instead of using both. The implication is that our smartest and closest animal relatives are unable to think of even the very near future as containing multiple alternative possibilities in such a way as to enable them to prepare for both — unlike human children (past the age of 3), who succeeded where the apes failed.

The matrix of maybe is specifically understood as pertaining to the future and not the past. To be sure, there are instances of uncertainty about the past, such as when a trial seeks to ascertain whether the defendant had indeed committed a particular crime. Yet the assumption is that there is an objective, unchangeable fact (either the person really did or really did not commit the crime), and the uncertainty lies solely in present knowledge about it. The multimaybe future, in contrast, is assumed to genuinely contain alternative possibilities.

Evidence for the multimaybe matrix in ordinary people's thinking was reviewed by Baumeister et al. (2018). People act as if the future is more changeable and more controllable than the past, even when subjective knowledge is equal. For example, people will bet more on a sports event that has not happened yet than on one that

is over, even though they are fully unaware of the outcome in either case (e.g., Brun & Teigen, 1990). People also seem to believe that they will have more free will in the future than they had in the past (Helzer & Gilovich, 2012), which may clarify the importance of present action. Indeed, planning is based on knowing that multiple futures are possible, so that it is helpful to make plans that will produce the desired outcome. Precommitment devices, such as a savings plan that automatically takes money from a paycheck and deposits it into a savings account, deliberately restrict the matrix of maybe so as to improve long-range benefits (having money for future purposes) by eliminating some tempting options in the near present (such as to spend one's entire paycheck on current activities). On average, people who use precommitment strategies tend to reach their goals more often than those who do not (Duckworth et al., 2018).

An implication of the precommitment benefits is that having more possibilities is not always or necessarily better. By and large, people do prefer to have more options and greater freedom. But there can be too many choices or options in general, and there can be particular options that cause trouble (and hence would best be eliminated).

Furthermore, traits such as optimism rest on a matrix of maybe. Optimism applies in situations where both good and bad outcomes are possible (and subjectively boosts the probability of a good outcome). Recent work suggests that future optimism is intuitive, as the first expectation that comes to mind is anchored on what the person *wants* to happen (Sjåstad & Baumeister, 2021). When engaging in a slower process of conscious reflection, second-guessing the future so to speak, humans can simulate a broader set of alternative possibilities which also include undesirable scenarios and what can go wrong (see also: Bear et al., 2020).

Morality is of particular relevance for the matrix of maybe. Moral judgments essentially ask whether the person should have done something different, and so they mainly apply in situations with multiple possibilities. If the person did not have alternatives, moral responsibility and condemnation are much reduced. Likewise, the

most discussed and researched moral dilemmas also rest on a matrix of maybe, as in multiple alternatives among which the person must choose. As two classic examples, people debate whether a poor man should steal medicine to save his sick wife's life, and whether a person should flip the switch to divert a runaway trolley to an alternate track, where it would kill one person rather than the five who are in its current path. Without a future of multiple possibilities, there would be no meaningful "dilemma" or real choices to be made, and in consequence, little room for personal responsibility. In contrast to that view, it is a widespread assumption that people *do* have an element of choice, which explains why the average person is inclined to moralize these actions by prescribing appropriate rewards and punishments. Indeed, people view others as less moral and less trustworthy to the extent that they even look like they have failed to exercise volitional will rationally (i.e., are obese and assumed to have failed to use self-control; Maranges et al., 2021).

Human beings are not only able to imagine various alternate future scenarios that could ensue from their current actions. They are also able to evaluate these. Damasio (1994) reported cases of people with brain damage that prevented emotional responses. These patients were still able to mentally imagine the full variety of possible future actions and consequences — but they had considerable difficulty making up their minds as to which was the best choice. This has led to the theory that an important function of human emotion involves imagining the future and anticipating how one will feel. For example, people may avoid actions that they deem likely to bring feelings of guilt or regret, whereas they may choose to act in certain ways based on anticipating that these will bring joy and satisfaction (Baumeister et al., 2007).

Having multiple options is widely seen as desirable. Already in the 1960s, social psychologists had shown that people dislike having their options restricted and will resist, sometimes aggressively (Brehm, 1966). Studies of decision-making show that people like to preserve their options, even to the point of being willing to pay

something to keep options available — even though they think it is unlikely they will use those options and in fact do not take them later in the experiment (Shin & Ariely, 2004). Even a false belief that one has an escape option and could terminate a bad situation reduces the amount of stress people feel (Glass et al., 1969). Although some of these findings may appear irrational or self-defeating when considered in isolation, they are part of a larger pattern of mentally preserving the future as a set of alternative possibilities. In short, humans are able to construct the future as a *matrix of maybe*, and thinking this way is generally helpful in planning, decision-making, and social life.

Abstract

This entry provides an introduction to the history, methodology, philosophy, science, and various types of meditation, which most traditions and practitioners view as broadening the range of transformative human possibilities and invoking exceptional human experiences. “Meditation” is a multiply ambiguous term, referring to a broad range of practices and mental states, many of which share common elements, such as heightened, focused, or tranquil awareness. While meditative states can arise spontaneously (Dass, *Journey of awakening: a meditator's guidebook*. Bantam Books, New York, 1978), meditative traditions teach that a practice of engaging in meditative discipline increases the likelihood of bringing about meditative states. For example, one common meditation practice, one-pointedness, consists of training one's attention to remain focused on a singular object, such as the breath, although any focal point will do. Long-term practitioners

report that this practice tends to bring about states of mental quiescence. Various forms of meditative practice have been associated with most of the world's major religious and spiritual traditions, particularly Buddhism, Hinduism, and Taoism, but monotheistic religions consider prayer a form of meditation. Alongside Yoga, which involves a form of meditation, secular forms of meditation have become increasingly popular in recent years, most prominently mindfulness. Jon Kabat-Zinn popularized mindfulness by creating MBSR, mindfulness-based stress reduction, an 8-week meditation program that studies have shown to have significant results reducing stress. Mindfulness alone has become a multi-billion-dollar industry, a fact bemoaned by traditional practitioners and others, who object that the practice endorses the idea that the appropriate way to deal with external stressors, such as societal injustice, is to alter one's internal responses, as opposed to altering external conditions. This entry examines all of these ideas in some depth.

Keywords

Mindfulness · One-pointedness · TM · MBSR · Philosophy

The term “meditation” is multiply ambiguous. Prior to the recent popularity of seated, eyes-closed meditation, the term has been used traditionally in the West to refer to a kind of philosophical, literary, or otherwise intellectual reflection or treatise, either in general or on a particular topic, as in Marcus Aurelius's *Meditations* or Rene Descartes's *Meditations on First Philosophy*, respectively. Aurelius's *Meditations* consists of standard journal entries, a reflective practice encouraged within Stoicism, the ancient Greco-Roman philosophical school of thought most widely known for advocating acceptance, although that view is partial and misleading. The key insight of Stoicism is the distinction between what is and is not within the range of our control, with an emphasis on what we can control together with an acceptance of what we cannot. The Stoic practice of nightly reviewing and

journaling about the day in retrospect is meant to call to light ways in which one can more effectively manage what is within one's power and accept what is not. Descartes's *Meditations on First Philosophy* is a complex philosophical work that encourages deep reflection on our beliefs, presuppositions, and the grounds of knowledge (Descartes 1993). The more widespread, recent usage of the term refers to a broad range of contemplative practices exemplified by practitioners of Yoga, Buddhist monks, and just about anyone else typified by sitting with eyes closed and legs crossed, engaging in some sort of metacognitive activity involving paying heightened attention to their breath, thoughts, bodily sensations, or chanting a mantra, engaging in prayer, repeating affirmations, or breathing in a controlled manner, among many related practices designed to bring about altered states; see the entries on ► [“Flow”](#), ► [“Spirituality”](#), and ► [“State of Consciousness”](#) in this Encyclopedia. It is this latter meaning that is the focus of this entry, although both meanings share conceptual elements and thus will be explored.

It is philosophically challenging to completely identify all and only those elements in common across these different uses of the term, but one Buddhist meditation teacher's definition of mindfulness meditation might suffice: “*extraordinary attention to ordinary experience*” (Dena 2003); see the entry on ► [“Mindfulness”](#) in this Encyclopedia. By “extraordinary” here, all that is meant is “more than ordinary,” or “heightened,” as opposed to “spectacular,” although some meditative states are spectacular. Thus, Aurelius, Descartes, the Buddha, and the multitude of yogamat-carrying contemporaries are all practicing forms of meditation, whether reflecting on the day behind them, the justification of beliefs, the nature of existential confusion, or stress-reducing somatic practices, respectively. Mindfulness is the contrary of mindlessness, a significant absence of awareness of what one is doing or experiencing. There is a spectrum of mental states, roughly, from mindless to mindful, and any state of mind that is not completely mindless exhibits some degree of awareness; cf. the entry on ► [“Mind Wandering”](#) in this Encyclopedia, however, on

the benefits of distraction and the idea that mind-wandering is a feature of a healthy mind rather than a bug. But the mere presence of an element of sentience or awareness is not necessarily indicative of a meditative state. Thus, the qualifier, “extraordinary,” in the simple compound sense of that term, “above ordinary,” captures the inclusive meaning of “meditation” – *heightened* awareness.

Despite the inclusive sense of the term covering the spectrum of its overlapping senses, some nonetheless divergent uses of the term appear at odds with each other. Some yogic forms of meditation, for example, involve eliminating thought, whereas some philosophical forms of meditation involve heightened states of discursive analysis. From the perspective of each of these, the other seems opposite, yet both involve heightened awareness, marked differences notwithstanding.

Traditional Western and Related Senses of the Term

Anything from a short poem to a book-length treatise on any subject can appropriately be entitled a “meditation on” that topic, e.g., violence, love, leisure, etc. Many of the entries in this Encyclopedia may be considered meditations in this sense; see, e.g., the entries on ► [“Liminality”](#), ► [“Emotion”](#), or ► [“Daydreaming”](#). Prior to the explosion of interest in Eastern forms of meditation, this usage of the term was perhaps the most popular one in the West. This entry focuses on Eastern meditation, but the above-mentioned works of Aurelius and Descartes, which have this more generic meaning, will be explored in some detail because they also capture elements of the broader meaning of the term.

Aurelius and the Stoics

Aurelius and other Stoics encouraged nightly journaling as a contemplative, reflective practice designed to heighten awareness of the distinction between what can and cannot be controlled, which they refer to as “the dichotomy of control.” The serenity prayer is based on this idea:

God, grant me the serenity to accept the things I cannot change; the courage to change the things I can; and the wisdom to know the difference.

The Stoics also engage in meditation practices that more resemble Eastern practices, such as “*pre-meditatio malorum*,” a morning practice whereby one visualizes the day ahead, imagines how something could go awry, and anticipates ways of responding skillfully. Another practice similar to Eastern meditation, the “*big picture meditation*,” involves visualizing the infinite cosmos, both spatially (infinity) and temporally (eternity), and viewing one’s place in life *sub specie aeternitatis*, thereby putting things in perspective; see the entry on “Simulation” in this Encyclopedia. (There are similar Buddhist and Hindu meditations on space and time.) Stoicism is undergoing a contemporary revival in the West (Pigliucci 2017), likely due to its resembling Buddhism, on the one hand, while being agnostic, naturalistic, and Western, on the other hand.

Rene Descartes and Other Philosophers

Descartes’s *Meditations on First Philosophy* contains six philosophical reflections on the nature of our knowledge of reality. His first meditation, “Of the Things That May Be Called into Doubt,” calls attention to the fact that he finds himself possessed of countless beliefs, many of which he realizes have been wrong, and notes that if one can doubt any particular belief or class of beliefs, such as those based on perception, then those beliefs may be incorrect. Implicit is the idea that knowledge is certain, doubt is uncertain, the same belief cannot be both certain and uncertain, and thus if one can doubt a belief, one does not know it to be true. Descartes then uses this “method of doubt” to test all of his beliefs, differentiating between those he can and cannot doubt, and attempting to establish a new philosophy built on solid, indubitable foundations; see the entry on “Uncertainty” in this Encyclopedia. Descartes notes that this sort of contemplation requires inactivity and solitude. Deep reflection on the nature of reality counts as meditation in the inclusive sense of extraordinary attention to ordinary experience; see the entries on “Inquiry,” “Reality,” and “Wisdom” in this Encyclopedia. All philosophical inquiry does, arguably.

Monotheistic Religious Traditions and Related Contemplative Practices

Within the Abrahamic monotheistic religious traditions (Judaism, Christianity, and Islam), prayer is considered a form of meditation, precisely because mindless repetition of phrases that constitute the content of prayers is technically not considered actually praying, but simply repeating words without thought. Thus, unlike certain Eastern meditation techniques that aim at stopping thought, prayer is discursive: the meaning of the prayer is central. However, prayer and mantra, the repetition of a prayerful word or phrase, can overlap, if both lead to trance-like states. In an embodied form of prayer, whirling dervishes, Muslim mystics of the Sufi order, dance in a circular pattern, aspiring to enter a state in which discursive thought is replaced by spiritual communion or grace. Similarly, in Hasidic Judaism, swaying during prayer is a way of intensifying devotion and triggering ecstatic spiritual states, as are prostration, kneeling, and other bodily movements in many religions, as well as in Yoga, Tai Chi, Chi Kung, etc. Tribal dance, enhanced by chanting, drumming and related musical forms, seems to be a much older if not more universal practice among native peoples the world over, suggesting a deeper connection between bodily movement and spiritual aspiration; see the entries on “Possible in Religion,” “Trance,” and “Spirituality” in this Encyclopedia. On some views, all spiritual practices are rooted in the same experience (Patyaying 2008).

One meditative practice in Western religious traditions that may move from the discursive to the nondiscursive is *lectio divina* (“divine word”), engaged by working through a scriptural passage in three stages: First, the passage is read aloud; second, silently; and third, the practitioner becomes receptive to any impressions arising therefrom by dwelling upon its meaning, guided by the spirit. A similar practice involves sitting quietly, listening to “the still, small voice within.” There are many variations on these practices (Zajonc 2009).

Traditional Eastern Senses of the Term

The Taoist philosophy of the natural balance between, and ultimate unity of, all polar

opposites, represented as *yin* (–) and *yang* (+) forming a circular unity, informs Taoist meditative practice, as well as Chinese martial arts such as Tai Chi, flowing yogic practices such as Chi Kung (see the entry on “Flow” in this Encyclopedia), and medicine such as acupuncture and herbal remedies. Tai Chi and Chi Kung function as embodied meditation in motion, not unlike Hindu Yoga, Hasidic davening, Sufi whirling, etc. Taoist meditative practices resemble yogic practices insofar as they involve breathing exercises, bodily movements, and postures.

The two related Asian religious philosophies that take meditation to be the supreme spiritual vehicles, however, if not spiritual sciences, are Hinduism and Buddhism. Indian art depicts yogis in meditation poses as early as 5,000 BCE, and Vedic scriptures, thought to be compiled after centuries of oral tradition, mention meditation several centuries before the life of the Buddha. The standard historical view of the relationship between Hinduism and Buddhism is that the latter is a modification of the former, based on the above and the fact that the Buddha himself claims to have learned yogic meditation techniques from two then-traditional teachers. The techniques he attributes to his teachers closely resemble those described in the *Yoga Sutras* of the Indian sage Patanjali around 150 BCE, which may be described as concentrative. The Buddha claimed that while those techniques brought him into deep meditative trance states (see the entry on “Trance” in this Encyclopedia), they did not bring him to full enlightenment. His teaching emphasizes their necessity, but that they alone are insufficient as meditation techniques. What else is needed, he taught, was a more expansive technique, mindfulness, among six other (nonmeditative) factors constituting his eightfold path for attaining *nirvāṇa*, spiritual enlightenment. Because this entry is primarily about meditation, the other six factors in the Buddhist eightfold path will be set aside.

Concentrative meditation, also known as one-pointedness, constitutes the main form of yoga meditation, although there are other forms of Hindu meditation. One-pointedness and mindfulness meditation, also known as open monitoring, constitute the two main forms of Buddhist

meditation. There are significantly different understandings and thus different descriptions of both techniques, and many variations on each, at least as many as there are different forms of Hinduism and Buddhism. For that reason, however, the focus here must be at a certain level of abstraction that glosses over such differences, not to suggest that such differences do not matter to practitioners of differing traditions – they do, but such differences do not bear on this analysis.

Simplifying for purposes of understanding, one-pointedness involves focusing attention narrowly on any single attentional object, such as the breath, a candle flame, or a word; mindfulness involves focusing broadly on any and all phenomena that enter the field of awareness or stream of consciousness. With one-pointedness, the intention is to maintain attentional focus on the chosen attentional target, which is always some narrow subset of the total field of awareness: whenever attention slips out of focus from the narrow target, one intends to notice that and redirect attention to the narrow target. With mindfulness, the intention is to maintain attentional focus on the attentional target, which is always whatever is occurring in the entire field of awareness: whenever attention slips out of focus from the broad target, one intends to notice that and redirect attention to the broad target. This technique is sometimes described as open monitoring, witnessing, or bare seeing. Because both techniques involve maintaining attentional focus, one narrowly and the other broadly, they may be considered ultimately two aspects of the same technique.

In both Yogic philosophy and Buddhism, one-pointedness is thought to lead to deep trance states of mental quiescence; see the entry on “Trance” in this Encyclopedia. In the opening line of the *Yoga Sutras*, for example, Patanjali claims that the essence of Yoga is this: *yoga citta vritti nirodha* (*yoga*: union; *citta*: consciousness; *vritti*: perturbations/fluctuations; *nirodha*: cessation) – meditative union is brought about by the cessation of thoughts. Patanjali goes on to describe various modifications of this technique thought to lead to different forms of spiritual fruition. In Buddhism, one-pointedness is the primary technique for bringing the practitioner into meditative trance

states of mental quiescence (Pāli: *jhāna*; Sanskrit: *dhyāna*), thought to signify stages of spiritual fruition. Different forms of Buddhism emphasize one or the other technique, or unite them.

One form of Zen meditation practice, “just sitting,” may be described as open monitoring, the broader form of practice associated with mindfulness, but other forms of Zen practice involve focusing on breathing, which involves one-pointedness. Tibetan Buddhist meditation techniques, however, can be complex, similar to some forms of Yoga meditation, involving a combination of one-pointedness practices, such as taking certain bodily postures, visualizing “chakras” (psychic energy centers similar to acupuncture points), chanting mantras, and controlled breathing, among other complex techniques; see the entries on “Possible in Religion” and “Spirituality” in this Encyclopedia.

Meditation techniques play a prominent role in Hinduism, Buddhism, and Taoism. Apart from monastics within these traditions, however, most Hindus, Buddhists, or Taoists do not practice meditation on a regular basis, contrary to popular assumptions (Flanagan 2011; Sharf 2014).

Contemporary Western Senses of the Term

There has been sporadic contact between Asian meditative traditions and the West as far back as the Alexandrian empire (Beckwith 2015). Schopenhauer, Thoreau, and Emerson, among other prominent Western intellectuals, were attracted to Eastern meditation. Swami Vivekananda, Swami Yogananda, and Shunryu Suzuki were among some of the first early representatives of Eastern meditation practices who came West between the nineteenth and twentieth centuries. Next, the Beat generation took an interest in Zen, followed by the Beatles’ flirtation with the Hindu guru, Maharishi Mahesh Yogi, who taught TM, transcendental meditation, spurring a wave of broad cultural interest in Yoga and meditation, which included Richard Littleman’s TV series *Yoga for Health*, Ram Dass’s popular book *Be Here Now*, Robert Pirsig’s classic novel *Zen and*

the Art of Motorcycle Maintenance, Swami Satchidananda’s appearance at Woodstock, the Hollywood celebrities’ guru Swami Muktananda, and, among others, Swami Prabhupada’s appearance at be-ins, introducing the Hare Krishna chant. A more recent wave of interest was sparked by celebrities like Oprah Winfrey, who invited various representative figures onto her popular TV show, including Deepak Chopra, Eckhart Tolle, Ram Dass, and others (Hammond 2018).

In 2013, the music of Krishna Das (Jeff Kagel), a renowned *kirtan* (meditative devotional chanting) master celebrated in the global Yoga community, was nominated for a Grammy Award for Best New Age album. Yoga and meditation are now mainstream: many millions of Westerners practice some form of meditation, and as many if not more practice some form of Yoga. The most popular forms of meditation appear to be TM, mindfulness, and Zen. TM consists of a private, personalized Sanskrit mantra (word or phrase) repeated in sync with the in-breath and out-breath, while sitting still with eyes closed, for about 20 minutes, once or twice daily. Studies suggest TM is effective with stress reduction. Dr. Herbert Benson (1975) of Harvard studied practitioners and extracted a generic, secular version of the practice using any word or phrase, which he termed “the relaxation response”, with similar results.

The broadest dissemination of meditation techniques in the West, however, above Zen, TM, and yogic meditation, owes to Jon Kabat-Zinn’s secular adaptation of Buddhist meditation techniques in his mindfulness-based stress reduction (MBSR) program, as well as his popular books (1994). MBSR is an adaptation of one-pointedness and mindfulness, although the MBSR narrative emphasizes mindfulness. According to MBSR, mindfulness consists of anchoring attention on breathing, which Buddhism considers a form of one-pointedness, while being non-judgmentally mindful of the comings and goings of various elements of consciousness, such as thoughts, intentions, emotions, sensations, memories, and so forth – in short, being present with whatever is, in the moment.

MBSR is derived primarily from a modern Burmese form of early Buddhist (Theravādin) meditation called *Vipassanā*, which literally translates as “insight,” but informally translates as “mindfulness,” since mindfulness is thought to lead to key insights believed to lead to enlightenment; see the “Insight” entry in this Encyclopedia. *Vipassanā* was made popular by Burmese meditation master S.N. Goenka, who modified the more traditional practice to make it more suitable to Westerners (Sharf 2014), a number of which brought it back to the West after taking Goenka’s free 10-day meditation retreats in India in the 1960s and 1970s, including Sharon Salzberg and Joseph Goldstein, founders of the Insight Meditation Society in Barre, Massachusetts, as well as Jack Kornfield, Ram Dass, Daniel Goleman, and other prominent *Vipassanā* teachers and meditation researchers.

In one form or another, mindfulness has become the most widely practiced form of meditation in the West in the past two decades, with many millions of practitioners, several very successful meditation apps, such as *Calm* and *Head-space*, and a multi-billion-dollar industry. Even Sam Harris, the controversial neuroscientist, pop philosopher, and podcast host has a meditation app. Google, the military, the corporate boardroom, various police and fire departments, school systems, sports teams, hospitals, prisons, mental health professionals, and other mainstream societal institutions and prominent public figures practice it.

Objections and Replies

As with anything else, once something becomes prominent, it invites criticism. Criticisms of meditation go back to Gilbert Ryle (1949), the behaviorist philosopher who rejected the idea of introspection on the ground that observing one’s mental state of, say, rage, would interfere with it. Another philosophical objection owes to Robert Nozick (1981), the Harvard libertarian philosopher who argued that, absent any supramundane ideology, the meditative state is of no more significance than the cognitive equivalent of a

soundless stereo system that is on but the stylus is not touching the rotating vinyl. Nozick admitted, however, that what cannot be as easily dismissed is that practitioners who have deep meditative experiences find them transformative, exhibiting powerful altruistic tendencies suggestive of something deeper than the mere experience of what it is like to damp down the cognitive apparatus. In line with Nozick’s observation of altered behavior, a recent meta-study of the 50 most-cited meditation research publications notes that long-term practitioners transition from the enjoyment of altered states to stable altered traits (Goleman and Davidson 2017). Apparently, contrary to both Ryle and Nozick, meditation is not “all in the mind,” so to speak, but it actually alters the brain, body, and behavior, in lasting ways (Begley 2007).

Ryle’s objection is technically valid, but whereas he saw this as a reason to reject meditation as incoherent, practitioners see his point as a reason to embrace it – precisely because calmly observing one’s mental states can have a diminishing influence on their ability to overpower reason, trigger destructive emotion, and propel one into unskillful action (Goleman 2003); see entry on “Emotion” in this Encyclopedia. Indeed, many proponents of MBSR and related meditation techniques appeal precisely to their ability to enhance wholesome forms of agency, if not to diminish weakness of will and increase functionally effective agency or free will (Federman and Ergas 2018; Harvey 2007; Meyers 2017; Repetti 2017, 2019; Wallace 2017); see entry on “Agency” in this Encyclopedia. Departing from the initial skepticism of philosophers like Ryle and Nozick, however, many prominent Western philosophers have begun to embrace meditation and related elements of Asian philosophy (Coseru 2012; Flanagan 2011; Garfield 2015; Repetti 2019; Siderits 2007; Strawson 1986; Thompson 2017). More broadly, academia has increasingly come to embrace meditation and related contemplative practices, significantly due to the work of the Association for Contemplative Mind in Higher Education (ACMHE), a multidisciplinary professional academic association established by the Center for

Contemplative Mind in Society in 2008, which has connected well over 800 educators, staff, graduate students, and administrators in 24 countries.

Apart from Ryle and Nozick's philosophical criticisms of meditation, more recent criticisms are directed at secular meditation, particularly mindfulness, once mindfulness became increasingly popular in almost every segment of Western society. In "Beyond McMindfulness" (2013), Ron Purser and David Loy popularized the term "McMindfulness" as part of a general critique of the embrace of secularized mindfulness practices in Western society. Purser and Loy are both long-term practitioners of Zen Buddhism; Loy is a Zen teacher. Recently, Purser published a book-length version of the argument (2019).

The criticisms amount to two main objections, on analysis, although there are many different versions of both (Burke et al. 2016). The first is that secular mindfulness is a blend of stealth Buddhism, that is, Buddhism disguised as a secular practice, on the one hand, and that it is too watered down to deliver the benefits of genuine Buddhist practice, on the other hand. These two aspects of the first criticism are at odds with each other, so they need not be taken seriously (Repetti 2016). The second main criticism is that the practice fits too nicely with consumerist capitalist culture, thereby perpetuating the inequities of the status quo by transmuting the discordance that might otherwise lead to social change by simply redirecting it through stress reduction techniques that suggest that the proper way to deal with inequities is by adjusting one's internal responses to them, as if they fell into the Stoic category of things that we need to learn to accept but which are truly in the domain of things we can change.

What such criticisms tend to ignore is the fact that Buddhism is equally guilty of this objection, if not more so, as is almost every religion, as history has made amply clear. Religions rarely challenge the status quo. As Jesus famously put it, "Render unto Caesar what is Caesar's." Inasmuch as some forms of mindfulness may be guilty of containing an element of stealth Buddhism, such criticisms of mindfulness arguably involve not-so-stealth ideological elements of

socialist criticisms of capitalist society – not to suggest that there is no merit to any such criticisms, but rather to keep the issues clearly and distinctly apart. Arguably, the Western societal embrace of secular mindfulness – which includes an embrace of neuroscientific research into which forms of meditation produce which empirically verifiable results (Goleman and Davidson 2017), as opposed to simply appeals to pre-modern religious superstitions – promotes more effective individual agency, as opposed to more milk-producing metaphorical cows (Repetti 2010, 2016, 2017, 2019).

Concluding Meditations

To the extent that mindfulness and related meditative practices increase the tendency to be mindfully present in one's moment-to-moment experiences, aware of their meaning and importance, and attentive to their potential implications, as opposed to being so busy multitasking that one is relatively mindlessly juggling between the most momentarily pressing elements of one's experience, meditative practices seem intuitively wholesome. However, recent studies have shown that certain individuals report challenging experiences associated with certain types of meditation, particularly during long-term meditation retreats involving several hours of intensely disciplined daily practice among otherwise non-long-term practitioners (Lindahl, Fisher, Cooper, Rosen, and Britton 2017), as might be expected, ironically, on reflection. However, mindfulness-based cognitive behavioral therapy (MBCBT) and almost every other major form of psychotherapy have endorsed and/or adopted some form of mindfulness as a therapeutic intervention, with positive results (Goleman and Davidson 2017).

Meditation is immensely popular for a reason: for most practitioners, it provides access to an aspect of being that the Taoists would describe as returning to the root of being, being itself, or just being – just sitting, being here now, as the Zen tradition emphasizes. Once Ram Dass – author of the classic *Be Here Now*, former Harvard psychologist Richard Alpert turned psychedelic

researcher, turned Hindu yogi and informal guru to the Baby Boomer generation – was asked what he thought was most salient for him about meditation after teaching and practicing it for the bulk of his adult life. He replied that he noticed its impact mostly by contrast with periods of his life when he was not practicing regularly, when he found himself walking around with a lot of “undigested experiences.” Recalling Nozick’s objection to the effect that meditation is nothing special, if nothing else meditation at least serves this function: it supports existential digestion. As the many other studies cited above suggest, this is perhaps its least effective role.

Finally, the Sanskrit word for “mindfulness” is *smṛti*, which also signifies *remembrance*, a calling to mind, associated with intimate familiarity based on experience. If nothing else, meditation offers the practitioner an opportunity to remember and honor the importance of becoming intimately familiar with one’s own mind, emotions, and body from the inside, of remembering oneself, of becoming comfortable with oneself, of being present in one’s experience in the here and now. In the present digital age of multitasking, with its tendency to spark FOMO (“fear of missing out”), it is no surprise that many millions turn to meditation for a wholesome alternative.

Abstract

Mental time travel research has given rise to an ongoing debate between causal and simulation theories of memory, which has, in turn, triggered a debate between continuist and discontinuist views of the relationship between remembering experienced past events and imagining possible future events. Section “[Introduction](#)” of this entry describes the concept of mental time travel and reviews both debates, distinguishing between processual and attitudinal forms of continuism. Section

“[Processual \(Dis\) Continuism](#)” reviews empirical evidence and metaphysical and epistemological arguments for processual continuism and discontinuism. Section “[Attitudinal \(Dis\) Continuism](#)” reviews the emergence of attitudinal continuism and discusses its relationship to processual continuism and discontinuism and to causalism and simulationism. Section “[Summary](#)” provides a brief summary of the entry.

Keywords

Mental time travel · Episodic memory · Episodic future thought · Imagination · Simulation theory of memory

Introduction

Mental time travel research has given rise to an ongoing debate between causal and simulation theories of memory (see ► “[Constructive Memory](#)”), which has, in turn, triggered a debate between continuist and discontinuist views of the relationship between remembering experienced past events and imagining possible future events (see ► “[Imagination](#)”). This section describes the concept of mental time travel and reviews both debates, distinguishing between processual and attitudinal forms of continuism.

Mental Time Travel

When Tulving (1972) first introduced the notion of *episodic memory* in psychology, he defined it as pertaining to the “what,” the “when,” and the “where” of experienced past events. This “WWW” definition was meant to differentiate episodic memory both from nondeclarative memory (including memory for habits and skills) and, within the category of declarative memory, from semantic memory (memory for facts). The definition was broadly compatible with existing philosophical approaches to memory, including the influential causal theory (Martin and Deutscher 1966), but it was ultimately unable to differentiate episodic memory from semantic memory, since the facts with which the latter is concerned sometimes bear on the what, the when, and the where of experienced past events.

The limitations of the WWW definition, together with accumulating evidence of an intimate relationship between remembering the past and imagining the future, led Tulving (1985) and others in psychology to redefine episodic memory as a form of *mental time travel* (MTT) in which the subject imaginatively re-experiences past events, just as, in episodic future thought, he imaginatively “pre-experiences” future events (see Prospection).¹ This MTT definition suggests that there is no deep difference between remembering experienced past events and imagining possible future events. The definition thus challenged the causal theory of memory, which takes the existence of such a difference for granted, and motivated a new post causal approach: the simulation theory (Michaelian 2016b).

Causalism and Simulationism

According to the *causal theory of memory*, the basic argument for which appeals to intuitions about hypothetical cases, a subject remembers just in case he satisfies previous experience, current representation, and appropriate causation conditions:

A subject *S* now remembers an event *e* if and only if

- S* experienced *e* when it occurred;
- S* now represents *e*;
- S*’s current representation of *e* is appropriately causally connected to *S*’s previous experience of *e*, where an appropriate causal connection is one that is sustained by a memory trace originating in *S*’s experience of *e*.

Like causalists, simulationists accept the current representation condition, but they reject both the previous experience condition and the appropriate causation condition. While there has been some

discussion of the consequences of rejecting the previous experience condition, the debate between causalists and simulationists has so far focused primarily on the appropriate causation condition and, specifically, on its necessity.

Michaelian (2016b) takes MTT research to have demonstrated that episodic remembering and episodic future thinking are processes carried out by the same episodic construction system. Episodic future thinking is a matter of imaginatively projecting oneself into the personal future. It cannot and therefore does not involve an appropriate causal connection between the imagined event and the subject’s current representation of it. Episodic remembering, Michaelian argues, is similarly a matter of imaginatively projecting oneself into the personal past. It can but need not always involve an appropriate causal connection between the remembered event and the subject’s representation of it. Michaelian thus takes MTT research to imply that appropriate causation is not necessary for remembering. What is necessary, according to the *simulation theory of memory*, is merely that the subject’s current representation be produced by a properly functioning (and hence reliable) episodic construction system:

S now remembers *e* if and only if

- S* now represents *e*;
- S*’s current representation of *e* is produced by a properly functioning and hence reliable episodic construction system that aims to produce a representation of an event belonging to *S*’s personal past.

The simulation theory has been the focus of direct attacks by causalists, but the causalism-simulationism debate has also triggered a more general debate regarding the relationship between remembering past events and imagining future events (Perrin and Michaelian 2017; Michaelian et al. 2020; Langland-Hassan 2021). Whereas the causal theory, which claims that appropriate causation is necessary for memory (but not for future thought), suggests that memory and future thought are deeply discontinuous, the simulation theory, because it rejects that claim, suggests that they are fundamentally continuous. Though

¹ In addition to episodic future thought, episodic memory is related to episodic counterfactual thought, in which the subject imaginatively experiences possible events that did not but could have occurred (De Brigard 2014). As counterfactual thought does not appear to raise any issues not raised by future thought, this entry focuses on the relationship between memory and future thought.

linked to the causalism-simulationism debate, the continuism-discontinuism debate has taken on a life of its own.

Continuism and Discontinuism

According to *continuism* (e.g., Michaelian 2016a; Addis 2020), there is, aside from their distinct temporal orientations, no fundamental difference between episodic memory and episodic future thought. *Discontinuism* is the denial of this claim: according to discontinuism (e.g., Debus 2014; Perrin 2016), there is a fundamental difference between episodic memory and episodic future thought. The continuist-discontinuist debate has focused primarily on remembering and imagining understood as processes, but the focus has recently begun to shift to memory and imagination understood as attitudes. Distinct *processual* and *attitudinal* forms of (dis)continuism have thus emerged. According to processual continuism, there is no fundamental difference between the process of remembering the past and the process of imagining the future; processual discontinuism is the denial of this claim. According to attitudinal continuism, there is no fundamental difference between the attitude involved in remembering the past and the attitude involved in imagining the future; attitudinal discontinuism is the denial of this claim.

The relationship of attitudinal (dis)continuism to processual (dis)continuism – and to the causalist and simulationist views with which processual discontinuism and continuism are associated – is discussed in the section “[Attitudinal \(Dis\)Continuism](#),” but note that the distinction between processual and attitudinal (dis)continuism presupposes that memory can be understood either as a process or as an attitude. Understood as a process, remembering might, if causalism is right, be broken down into the stages of encoding, consolidation, storage, and retrieval. If simulationism is right, remembering, strictly speaking, reduces to the retrieval stage responsible for the production of the subject’s current representation. Understood as an attitude, memory can be described in terms of the role played by retrieved content in the subject’s cognitive economy. There is room for disagreement over the

nature of this role, but one might hold that a subject takes the remembering attitude towards a retrieved content when he takes that content to correspond to a past event, or when he takes it to correspond to a past event that he experienced, or perhaps when he takes it to correspond to a past event that he experienced and to be available to him now because he experienced that event.

Processual (Dis)continuism

This section reviews empirical evidence and metaphysical and epistemological arguments for processual continuism and discontinuism.

Empirical Evidence

Continuists have cited a range of empirical findings in support of their view. Discontinuists have both contested the continuist interpretation of these findings and cited additional findings in support of their view.

Perhaps the most impressive evidence for continuism is provided by imaging studies that demonstrate the involvement in episodic memory and episodic future thought of strongly overlapping brain regions, suggesting that a single episodic construction system subserves both forms of MTT (Addis 2018). Additional evidence comes from a variety of other sources. Memory and future thought are organized in a similar fashion, with both past and future events being embedded in the same narrative structures (Rathbone et al. 2011). There are important phenomenological similarities between memory and future thought, as the level of detail and intensity of experience vary with temporal distance in a similar manner remembering and future thinking (Schacter et al. 2012). The capacities to remember past events and to imagine future events emerge in development at roughly the same age (Perner et al. 2010). Moreover, these capacities not only come online together, but they also tend to go offline together. Deficits in the ability to remember the personal past are correlated with deficits in the ability to imagine the personal future (e.g., Rosenbaum et al. 2005). Similarly, patients suffering from depression display parallel tendencies

to remember the past and to imagine the future in overly general ways (Williams et al. 1996).

Though imaging studies provide evidence for continuism, they also provide evidence for discontinuism, as they indicate that imagining is more cognitively demanding than remembering and draws on additional brain regions (Schacter and Addis 2007) and demonstrate that impairment of certain regions affects future thought but not memory (Berryhill et al. 2010). Indeed, some researchers have argued that two subsystems can be distinguished within the system responsible for MTT (Addis et al. 2009), while others have argued that imagining future events, in contrast to remembering past events, relies on conceptual knowledge to provide a scaffolding for the integration of episodic details (Irish et al. 2012). Moreover, there is evidence that remembering past events involves richer and more vivid detail than does imagining future or past events (De Brigard and Giovanello 2012). The emotional valence of remembered and imagined events displays a similar discrepancy, with the latter being characterized by a greater positivity bias than the former (Rasmussen and Berntsen 2013).

Overall, then, the available empirical evidence is insufficient to settle things decisively in favor of continuism or discontinuism. Nor is it clear that empirical evidence could, in principle, by itself suffice to settle things in favor of one or the other view. Continuists grant the existence of differences between memory and future thought, just as discontinuists grant the existence of similarities. The question over which they disagree is whether the differences between these two forms of episodic thought are *fundamental*. Since empirical evidence does not determine whether or not given evidence is fundamental, philosophical arguments may have a role to play in settling the debate. The following two subsections review philosophical arguments for and against two kinds of plausibly fundamental differences – metaphysical and epistemological – between memory and future thought.

Metaphysics

The phenomenon of *reference* in MTT might ground arguments for metaphysical continuities

or discontinuities between memory and future thought. If the causal theory of memory is right, then the reference of memories – the fact that they are about particular events – might be explained, in line with the causal theory of reference, by the appropriate causal connection that links memory to the event that it is about, whereas the reference of future thoughts would have to be explained in other terms, supporting discontinuism. If the simulation theory of memory is right, then the reference of both memories and future thoughts might be explained in the same terms, perhaps in line with the description theory of reference, supporting continuism. There is little published work so far on reference in remembering (but see Michaelian et al. (2020) for an exploratory treatment).

The primary considerations that have been invoked in favor of metaphysical continuities and discontinuities between memory and future thought pertain not to reference but rather to *representation*. There are two main competing views about the role of representation in memory. According to *relationalism*, when one remembers an event, one is directly related to it – the event is a constituent of the memory. According to *representationalism* (which was taken for granted in formulating the causal and simulation theories in section “Introduction”), when one remembers an event, one represents it – the event itself is not a constituent of the memory. The main argument in favor of relationalism pertains to the relational phenomenology of memory (Debus 2008): intuitively, when one remembers an event, it seems to one that one is aware of the event itself, not of a representation of it. The main argument in favor of representationalism pertains to memory error: one can remember not only accurately but also inaccurately (i.e., one can misremember), and one can even remember events that did not occur at all (i.e., one can confabulate); there is no apparent way of describing mismemory and confabulation without invoking (inaccurate) representations, which suggests that successful memory should likewise be described as involving (accurate) representations (Sant’Anna 2020). Relationalists typically respond to the

representationalist argument by biting the bullet and endorsing *disjunctivism*, according to which, because successful memories are constituted by the events that they are about, whereas mis-memories and confabulations are not, there is a fundamental difference between successful memory, on the one hand, and mismemory and confabulation, on the other (see Sant'Anna [Forthcoming](#)).

Relationalism and representationalism can be generalized to MTT as a whole, including future thought. On the one hand, given that future thoughts are about events that have not occurred and that might not occur, they are presumably not constituted by the events that they are about and will therefore be assigned by relationalists to the same disjunct as mismemories and confabulations (Sant'Anna and Michaelian [2019](#)). Relationalism thus entails the existence of an apparently fundamental difference between memory and future thought, aligning with discontinuism. On the other hand, there is no barrier to understanding both memory and future thought as involving representations of the events that they are about. Representationalism is thus compatible with the nonexistence of any fundamental metaphysical difference between memory and future thought, aligning with continuism.

Debus ([2008](#)) argues that relationalism aligns naturally with causalism, maintaining that the constitution relation that relationalists see as obtaining between memory and the event that it is about can be understood in terms of the appropriate causation of the former by the latter. (Note that adopting relationalism would require reformulating the causal theory's current representation condition.) Debus's position is critiqued by Aranyosi ([2020](#)), who argues that a relationalist must, strictly speaking, treat the constitution relation as fundamental. Aranyosi's position is itself critiqued by Moran ([forthcoming](#)), who argues that, while relationalists must treat the constitution relation as cognitively fundamental, they need not treat it as metaphysically fundamental and hence that they may, as is natural, take it to supervene on the appropriate causation relation. If Moran is right, then relationalism aligns not only with discontinuism but also with causalism.

Epistemology

One source of arguments for epistemological continuities and discontinuities is the potential *immunity to error through misidentification* of episodic memory and/or episodic future thought. A thought is immune to error through misidentification (IEM) just in case it is impossible for it to be fully accurate but for the thinker to be mistaken about his own identity with one of the subjects involved in the event. Perrin ([2016](#)) has argued that, because the identities of the subjects involved in a remembered event are causally determined, memory is not IEM, whereas, because the identities of the subjects involved in an imagined event are stipulatively determined, future thought is IEM. Perrin's view thus suggests that there is an apparently fundamental epistemological difference between memory and future thought, aligning with discontinuism. Fernández ([2019](#)), in contrast, has argued that, because the identities of the subjects involved in a remembered event are built into the content of the memory, memory is IEM. Presumably, if the identities of the subjects involved in a remembered event are built into the content of a memory, the identities of the subjects involved in an imagined event may be built into the content of future thought, in which case future thought, too, would be IEM. This extension of Fernández' view is thus compatible with the possibility that there is no fundamental epistemological difference between memory and future thought, aligning with continuism.

Another source of arguments for epistemological continuities and discontinuities is the potential *directness* of our knowledge of the future and the past. It is intuitively plausible that memory provides us with knowledge of past events that is of a different kind than the knowledge of future events with which future thought provides us – that, roughly speaking, our knowledge of the past can be direct, whereas our knowledge of the future can only be inferential (Swinburne [1966](#)). Attempting to explain this epistemic asymmetry, Kneale ([1972](#)) invokes the causal theory of memory, but the causal theory of memory does not entail the existence of the asymmetry unless it is combined with the causal theory of knowledge.

The causal theory of knowledge, however, has difficulty accounting not only for our knowledge of future events but also for a variety of other forms of knowledge (e.g., our knowledge of time-less facts). It thus enjoys little popularity and has been eclipsed by the reliabilist theory of knowledge, on which knowledge does not require causal connection but only reliability. The reliabilist theory of knowledge, combined with a simulationist approach that treats both memory and future thought as potentially reliable, is compatible with the nonexistence of an epistemic asymmetry between our knowledge of past events and our knowledge of future events (Michaelian 2016a).

Attitudinal (Dis)continuism

This section reviews the emergence of attitudinal continuism and discusses its relationship to processual continuism and discontinuism and to causalism and simulationism.

Sections “[Causalism and Simulationism](#)” and “[Continuism and Discontinuism](#)” suggest that the continuist-discontinuist debate ultimately turns on the necessity of appropriate causation for remembering and thus that a resolution of that debate depends on a resolution of the causalist-simulationist debate: if causalists are right in claiming that appropriate causation is necessary for remembering, then discontinuism is correct; if simulationists are right in claiming that appropriate causation is not necessary for remembering, then continuism may well be correct. Section “[Mental Time Travel](#)” suggested that empirical evidence is incapable of directly resolving the continuism-discontinuism debate. Empirical evidence might nevertheless be capable of resolving the causalism-simulationism debate: as noted in section “[Introduction](#),” the basic argument for causalism is based on intuitions, whereas the basic argument for simulationism is based on empirical MTT research. Empirical evidence might thus be capable of indirectly settling the continuism-discontinuism debate, with continuism being likely to prevail over discontinuism.

This line of reasoning may, however, be too simple. Sant’Anna (2021) argues that, if representationalism, which most philosophers of memory

endorse, is assumed, then a resolution of the causalism-simulationism debate would not entail a resolution of the continuism-discontinuism debate, for, if representationalism is true, then the necessity of an appropriate causal connection amounts only to a non-fundamental difference between remembering the past and imagining the future. Rather than turning on the necessity of appropriate causal connection, Sant’Anna suggests, the continuism-discontinuism debate should be understood as turning on the attitudes involved in remembering the past and imagining the future. Recent work has emphasized that, in claiming to remember an event, the subject claims epistemic authority with respect to that event (Craver 2020). It is thus plausible to take remembering to involve a certain attitude, and one might hold, as noted above, that the subject takes that attitude towards a retrieved content when he takes that content to correspond to a past event, or when he takes it to correspond to a past event that he experienced, or perhaps when he takes it to correspond to a past event that he experienced and to be available to him now because he experienced that event.

Though some have argued that it is a mistake to understand the continuism-discontinuism debate in attitudinal terms (Langland-Hassan [forthcoming](#)), the attitudinal approach has been increasingly popular (Munro 2021; Robins 2020; Schirmer dos Santos et al. [Forthcoming](#)). The approach nevertheless faces important challenges. On the one hand, it is not clear that, in claiming to remember an event, the subject necessarily claims epistemic authority with respect to that event. One can, in particular, reject a retrieved memory, which suggests that, when one remembers, one need not take one’s memory to correspond to a past event. On the other hand, it is not clear that the attitudinal approach renders continuism as unattractive as its advocates have supposed. If what it is to take the remembering attitude towards a given content is merely to take that content to correspond to a past event (and not necessarily to take it to correspond to an event that one experienced or to take it to correspond to an event that one experienced and to be available to one now because one experienced it), then remembering may be continuous with forms of future thinking

in which the subject takes his representations to correspond to future events. Attitudinal continuism, then, is a view worth exploring.

Summary

This entry has provided an overview of the causalism-simulationism and continuism-discontinuism debates to which MTT research has led. These debates have not yet been resolved. New varieties of both causalism and simulationism continue to be developed, as do new arguments for continuism and discontinuism. Efforts to clarify the prospects of attitudinal continuism and discontinuism, in particular, are ongoing, and, though considerable attention has been devoted to attitudinal discontinuism, the merits of attitudinal continuism remain largely unexplored.

Abstract

Mind wandering plays a significant role in the psychological construction of possible worlds. It has a functional connection with pretend play, autobiographical planning, and creativity. Because of its association with pretend play, mind wandering is a precursor of creativity and imagination. Additionally, mind wandering is involved in the preparation for alternative futures during autobiographical planning. Thus, it has a strong connection with autoeic awareness and episodic memory. Mind wandering is also related to idea generation during the incubation stage of the creative process. Moreover, during long-term endeavors, creative individuals adopt a disposition of mindful mind wandering. By advancing research on mind wandering, we will gain more knowledge about the multiple ways human beings transcend their current experience, in addition to open new inquiries about the relationship between consciousness, memory, and creativity.

A wandering mind is a mind that is closely connected with possible worlds. Smallwood and Schooler (2006) define mind wandering as “a situation in which executive control shifts away from a primary task to the processing of personal goals” (p. 946). In short, the mind wanders when attention is defocused from the task at hand by self-generated thoughts. Namely, mind wandering is what in our everyday life we sometimes experience as being distracted or diverted by the flow of our consciousness. However, this experience of distraction does not reveal the constructive influence mind wandering has in our mental life. Specifically, the process of mind wandering plays a relevant role in three psychological processes involved with the imagination of possible worlds: pretend play, autobiographical planning, and creativity.

Mind wandering is a dominant activity of our mental life that is present in a multiplicity of psychological conditions. The initial scientific studies of daydreaming proposed that people are in a state of mind wandering during a significant part of their waking life (Singer, 1974, 1975). Recent estimates found that people report that they are in a mind wandering state at roughly one third of the thought samples taken during their waking time (Kane et al., 2007; Killingsworth & Gilbert, 2010). Furthermore, mind wandering is also reported by participants in psychological experiments involving complex or demanding tasks (McVay et al., 2009; Smallwood & Schooler, 2015).

At the beginning of the current century, research provided converging evidence collected using functional magnetic resonance imaging (fMRI) on the nature of mind wandering. Specifically, researchers identified a brain network known as the brain’s default network (Buckner et al., 2008). This network is a baseline default mode of brain function during the awake but resting state that is suspended in goal-directed behavior (Raichle et al., 2001; Raichle & Snyder, 2007). Default activity is associated with mind wandering (Mason et al., 2007). This network has a connection with episodic memory as well. A group of brain regions overlapping the default network displays increased activity when people are remembering the past or imagining the future

(Beatty & Schacter, 2017; Schacter et al., 2007). This connection with episodic memory is very relevant to understand the functional relationship mind wandering has with some constructive psychological processes since some types of future oriented mind wandering have an adaptive value in our psychological life (McMillan et al., 2013).

Although some varieties of mind wandering are beneficial to our development, some others can be detrimental. Mind wandering is particularly disadvantageous for those activities requiring sustained attention, specially in learning contexts (Immordino-Yang et al., 2012; Smallwood et al., 2007; Szpunar et al., 2013). Not surprisingly, mind wandering has a negative impact on traditional educational activities such as attending a lecture (Lindquist & McLean, 2011), answering standardized assessments (Mrazek et al., 2012) and reading (Smallwood et al., 2008). Because of its impact on the learning process, mind wandering may create limitations in our capacity to acquire knowledge that is essential to carry out activities that are not only academically but also personally relevant. These limitations can be attenuated by developing meta-cognitive strategies and ways to re-engage with the main task (Preiss et al., 2019; Smallwood et al., 2007).

As noted by Smallwood and Schooler (2015), mind wandering includes cognitive processes that have been categorized under different concepts such as daydreaming (McMillan et al., 2013), task unrelated thought (Giambra, 1989), stimulus independent thought (Antrobus, 1968) and self-generated thought (Smallwood, 2013), among others. Notwithstanding it involves a wide range of phenomena, self-generated thought is more characteristic of mind wandering than other processes such as task unrelated thought (Smallwood & Schooler, 2015). As regards its measurement, mind wandering can be assessed as a trait or as a state (Seli et al., 2016). Trait mind wandering refers to the self-report of the frequency of mind wandering in everyday life whereas state mind wandering refers to the report of mind wandering in a specific situation, typically one that is produced in a laboratory setting.

Although mind wandering is a universal psychological phenomenon, it comes in many forms

and involves a variety of contents. Understanding the differences between types of mind wandering is informative of its relationship with the possible. Thus, mind wandering can be spontaneous or deliberate (Seli et al., 2015). Individuals that have an inclination to mind wander either deliberately or spontaneously in everyday life have a similar disposition to do so in laboratory settings (Seli et al., 2016). Other differences are caused by the moods associated with mind wandering. Although some types of mind wandering involve positive emotions, some others involve negative ones. Singer (1974, 1975) distinguished three types of mind wandering: one more positive, which involves elaborated imagery and fantasy and an acceptance of inner experience, and two more negative, which are focused either on tortured self-examination or anxious self-doubting. Evidence for negative types of mind wandering is also provided by studies on retrospective mind wandering. Researchers have noted that mind wandering may lead to unhappiness when it is focused on past events (Smallwood & O'Connor, 2011).

To understand the relationship between mind wandering and the imagining of possible worlds, it is necessary to focus on self-generated thoughts that accomplish an adaptive function in our psychological life. The types of mind wandering that help us to imagine possible worlds are those that are mostly future oriented, have a positive emotional valence and/or are connected with constructive idea generation. Specifically, there are three psychological processes that take advantage of the constructive nature of mind wandering: pretend play, autobiographical planning, and creativity.

Mind Wandering and Pretend Play

Mind wandering is present very early in human development since “mind wandering is a natural component of pretend play” (Russ, 2020, p. 231). And pretend play is connected with the generation of fantasies and creative imagination. One of the main features of pretend play is its *as if* concept. Objects and persons are treated *as if* they were other things or in different roles (Fein, 1987; Russ, 2020).

Pretend play has several positive impacts. It is a safe place for expressing affects whose content may be symbolized and articulated creatively (Russ, 2020). Accordingly, pretend play interventions in medical settings can help children cope with stressful health circumstances (Moore & Russ, 2006). In addition to its emotional benefits, pretend play creates situations where children can acquire general knowledge (Sutherland & Friedman, 2013) and develop their communication (Roby & Kidd, 2008). Pretend play also fosters young children emerging self-regulation and language skills (Whitebread & O'Sullivan, 2020). In turn, many of these skills foster the development of creativity. Whitebread and O'Sullivan (2020) suggest that the relationship between pretend play, self-regulation, language and creativity is bidirectional. Other studies have shown that pretend play predicts creativity 4 or even 7 years later (Lee & Russ, 2018; Russ et al., 1999; Wallace & Russ, 2015). Pretend play is related, additionally, with creativity in storytelling, taking into consideration verbal skill (Hoffmann & Russ, 2012). Certainly, the positive impact of pretend play on creativity and human development is based on its imaginative content. It is imagination what makes other possible worlds available to children during pretend play (Woolley et al., 2020).

Mind Wandering and Autobiographical Planning

Episodic memory and mind wandering are interlaced both biologically and psychologically. As mentioned above, brain regions overlapping the default network display increased activity when people reminisces the past or imagine the future (Beatty & Schacter, 2017; Schacter et al., 2007). Beatty and Schacter (2017) notice that this finding shows that episodic memory influences both retrieval processes as well as mental simulations of future experiences or events. Tulving (2002) noted that episodic memory involves a distinctive kind of conscious awareness, which he denominated *autonoetic awareness*. Tulving indicated that this type of awareness covers both the past and the future: in fact, brain damage

impairing episodic memory not only causes amnesia but also an inability to imagine the future. That is, amnesia impacts the entire subjective apprehension of time. This notion of episodic memory is consistent with the following assertion: “Transcendence (i.e., responding to something beyond the here and now) is common to both memory and foresight” (Baumeister & Masicampo, 2010, p. 957).

More specifically, mind wandering is consistent with activities of preparation for alternative futures. Research has shown that a significant part of mind wandering is future-oriented (Baird et al., 2011; Smallwood et al., 2009). As with other phenomena associated with mind wandering, cognitive ability makes a difference: people with a higher working memory are more likely to engage in prospective mind wandering (Baird et al., 2011). Additionally, mind wandering is helpful to future-oriented decision making: people that mind wander more show a decreased tendency toward delay discounting, that is, they have a preference for large rewards which require waiting for them over smaller immediate rewards (Smallwood et al., 2013). Thus, people that more frequently engage in mind wandering may be more aware of the value of long-term recompenses than people who are less mentally engaged with future events. In short, mind wandering is beneficial not only to imagining the future but also to inform our reasoning and decision making about those possible scenarios.

Mind Wandering and Creativity

Creative thinking has a close link with mind wandering as a state. Activity in the brain’s default network correlates positively with general intelligence and creativity (Takeuchi et al., 2011). Additionally, mind wandering seems to be particularly important during the incubation stage of idea generation. As revealed by a meta-analysis performed on 117 previous studies, tasks of divergent thinking benefit more from the incubation stage than linguistic or visual tasks. And a longer stage of incubation with a low cognitive load is more advantageous than a shorter stage of incubation

or one that involves a challenging task (Sio & Ormerod, 2009). Research has also shown that mind wandering occurrence during incubation correlates positively with the participants’ ability to generate solutions to problems whose goal is to test for creativity (Baird et al., 2012). Spontaneous mind wandering can facilitate the development of remote associations by reducing cognitive control. Thus, it makes more probable that problem solvers can find unexpected solutions.

Mind wandering as a trait is also connected with creativity. A study about the relationship between mind wandering, metacognition and creativity that tested 116 university students and 117 vocational students found that their level of mind wandering, assessed as a trait, predicted verbal creativity over the contribution of fluid intelligence, reading difficulties and declarative knowledge of metacognition strategies (Preiss et al., 2016). However, another study with younger high school students showed that mind wandering only boosted the creativity of those students who had a wider attention span and reported more use of metacognitive strategies (Preiss et al., 2019). Therefore, the impact of mind wandering on creativity is not isolated from other variables. Cognitive ability and metacognition are important determinants of how mind wandering impacts on idea generation, especially among younger individuals.

Mind Wandering, Real Life Creativity, and the Self

Most research on mind wandering and creativity has been implemented in laboratory settings instead of real life situations. Although these experimental studies have been instrumental to test several hypotheses about the influence of incubation on idea generation, they may still provide a limited picture of the way mind wandering impacts the creative process of professional or eminent individuals. Consequently, in order to better appreciate the role of mind wandering in creativity, it is necessary to look at its phenomenology in real life, especially during extended processes of innovation, invention or creation.

Many creators report that completing their most important work takes a significant amount of time. Evidence in favor of the protracted nature of creativity comes not only from the 10-year rule in the study of expertise and exceptional achievement (Hass & Weisberg, 2015), but also from numerous case studies of eminent creators, which show that they are involved in long-term networks of enterprise, such as did Darwin when creating his theory of evolution (Gruber & Wallace, 2001). According to Gruber and Wallace, the psychological dynamism of the creative networks of enterprise illuminates how the motivation to finish an incomplete task - the Zeigarnik effect - operates in real life. An eminent creator is always returning to what he or she considers his or her unfinished work. Therefore, to understand the role mind wandering plays in real life creativity, a long-term view of insight might provide a better framework than a short term approach that is restricted to an experimental setting (Cosmelli & Preiss, 2014).

As noted by Cosmelli and Preiss (2014) "there is a wide agreement that finding creative solutions, despite being usually characterized by a sudden and holistic 'Aha!' is not exhausted by this local, more overwhelming aspect of the experience" (p. 2). Based on this open-ended nature of insight in real life, Cosmelli and Preiss (2014) called attention to the "two sided past-closing/future opening structure" (p. 3) of the experience of insight. On the one hand, an insight closes a gap in the past and helps to make sense of previous posed problems. On the other hand, an insight changes the representation of a problem and, therefore, it opens a generative dynamic where new problems are presented.

As suggested, the attentional disposition that creators have in real life is not well-captured using standard behavioral measures that can only assess a circumscribed lapse of time. Therefore, in order to study how mind wandering influences creativity in long-term networks of enterprise, we need to study how creative problem solving and insight have been documented in case studies or personal testimonies (Csikszentmihalyi, 1996; Gardner, 1993). To illustrate, personal accounts of poets suggest authors are specially inclined to deliberately engage on mind wandering during

their creative writing (Preiss et al., 2020; Preiss & Cosmelli, 2017). Additionally, poets have noted that their writing process involves an attitude of mindful mind wandering:

"Professional creators develop a sense of identity that is strongly grounded on their awareness of the mind wandering process. As authors become more expert, they gain a better understanding of the creative process and apprehend its phenomenological nature. Specifically, they become mindful mind wanderers. That is, they make temporally extended insight problem solving a core part of their self and their life story." (Preiss & Cosmelli, 2017, p. 303).

By engaging in mindful mind wandering, poets build their own selves around the creative process. In so doing, they link the process of mind wandering with the larger dynamics involved in the creation of culture.

Conclusion

Mind wandering plays a central role in the psychological construction of possible worlds. It is a core part of pretend play, it is involved in autobiographical planning, and it is an essential part of the generative processes in creativity. It also plays a significant role in long-term networks of enterprise since creators are specially inclined to deliberately engage on mindful mind wandering.

Although we now have an understanding of the relationship between mind wandering and the imagining of possible worlds, there are three areas that require further research. First, more research on the developmental changes experienced by mind wandering across the life span is needed. Specifically, we need to increase our understanding of how constructive mind wandering evolves across development and how this evolution has an impact on other cognitive processes, particularly creativity. Second, we need to explore the role of mind wandering in the creative process beyond tasks tested in restricted laboratory settings. So far, case studies have provided us with a rich conceptual framework that helps us to understand creativity in long-term undertakings. Yet, to this date there are not real life studies focusing on how eminent creators engage deliberately in mind wandering to produce their work

and we mostly rest on biographical accounts to get a grasp of this process. Last but not least, we need to advance research to elucidate what is the relationship between mind wandering and episodic memory since this understanding might inform our comprehension of other psychological processes. To illustrate, creativity research does not usually explore the role of episodic memory in idea generation, although previous experiences may play a key role in real life creativity. Particularly, mind wandering may help creators to capitalize on these experiences in such a way that they get inspiration from them to generate new associations or to produce novel ideas. Thus, mind wandering might be the way muses manifest in an artist or a scientist's life. Yet they may lack any awareness that these muses come from their own experiences.

In summary, mind wandering plays an essential role in our imagining of the possible. Its influence is present very early in human development, it remains significant during the lifespan, and it leaves a distinctive mark in our creative endeavors. By advancing research on mind wandering, we will gain more knowledge about the multiple ways human beings transcend their current experience, in addition to open new inquiries about the relationship between consciousness, memory, and creativity.

Abstract

Mindfulness characterizes the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding experience moment by moment (Kabat-Zinn, *Wherever you go, there you are: Mindfulness meditation in every day life*. New York: Hyperion, 1994). Mindfulness, as a disposition or state developed through meditation, appears to be a relevant functioning for adaptation to a naturally stressful environment.

This contribution addresses the question of ecological human enhancement from the point of view of an individual's adaptation to environmental stresses focusing on mindfulness functioning. After distinguishing between the concepts of adaptation and enhancement, this chapter aims to provide a respectful view of health based on ecological principles of human function pursuant to three needs: (i) stress management, (ii) perception of the present environment and understanding the situation, and (iii) decision-making in conflicting situations.

Keywords

Mindfulness · Enactivism · Enhancement · Adaptation · Stress management

Introduction

The broad theoretical frame is enactivism, which targets experiences encountered, incarnated in the center of the relation between man and his environment as the instigator of the adaptation (Varela et al. 1991). This approach suggests a perspective

on an enhancement that respects the man's ecological abilities to adapt that mindfulness makes possible.

Indeed, from time immemorial, men have sought ways to be more powerful, to go faster and farther, to be more energetic and more efficient. Enhancement aims to develop an individual capable of increased performance quality and/or length of use whatever the environmental changes, and the level of stress. When the environment is perceived as too changeable, it becomes uncertain and therefore stressful, what emerges is a risk of a state of maladjustment which, if repeated, can lead to the development of psychopathologies. Stress is therefore both a cause and effect of the adaptation process to serve the individual's survival. Subsequently, any modification of the operation with the aim of human enhancement cannot state an outcome in a stable sense, but more of a dynamic interaction where the result is an enhancement at the time "t" for a specific given environment. Then, it is relevant to act for reducing the perceived stress for a decrease of the biological cost of living in a perceived stressful environment. The minimal cost is observed in a homeostatic operation, and any exposure to an aggressive environment leads to an additional price called allostatic load. The whole purpose of adaptation is to reduce this price. An "enhanced" human would be a person having greater proactive adaptation to his perceived environment.

The arsenal currently used for increasing potential of the individual is vast, notably with the emergence of neuroscience. However, for physicians, limitations for human enhancement are clearly defined by the Hippocrates oath, which as a last resort sets the medical conduct "primum non nocere." This makes it necessary to question the enhancement with a "what to do," in other words, by an essential evaluation of the relevance of the enhancement regarding the adaptation that the environment in which the man is living and acting. Wanting human enhancement can only be done by considering three inseparable risks: increasing a biological capacity without being sure of the absence of risk functional impairment, enhancing human nature, and

improving the way that an individual lives his or her life (meaning the person's fulfillment). Mindfulness, as a disposition or state developed through meditation, appears to be a relevant functioning for adaptation to a naturally stressful environment leading to a high level of fulfillment.

Mindfulness and Stress Response

Understanding Stress Factors and Reactions

A stress factor or a stressor characterizes any situation that activates a stress reaction, regardless of its nature, intensity, and duration. A stressor can be external to the subject, or generated by his or her own body. External stressors are imposed on the subject by a change in the environment. They are the most studied. Internal stressors (affects thoughts, etc.) receive less attention. Internal stressors mainly concern the endless worrying and brooding that takes place between stressful events: negative rumination. Rumination not only delays the recovery from a stress response but also can cause stress responses before the stressor even takes place due to our anticipation of this stressor: we are ruminating about it before it happens (Brosschott 2017). Such negative ruminations induced chronic stress response independent of the environment.

Stress reaction was first conceptualized by Hans Selye (1956) in the general adaptation syndrome in a model with three successive phases. (i) the first phase, known as alarm, corresponds to the activation of all the biological mechanisms according to a control pattern, triggering an explosive acute response of the stressor response. (ii) the second phase, known as the resistance, adjusts the stress response to the intensity of the perceived aggression according to sustained regulation (eustress). (iii) The third phase is a phase of biological exhaustion when the aggression is too intense for too long. It results in the apparition of illnesses, even death. Once the aggression disappears, a recovery phase ensues the stress. This stress response is based on biological reactions that enable an individual to connect to his/her environment. Mechanisms are mainly based on the secretion of glucocorticoids and activation of

the sympathetic nervous system that adjusts the stress response to the needs, and the parasympathetic nervous system supporting the recovery mechanisms. The regulation quality for each of these biological mechanisms is a fundamental point. In the alarm phase, a stress defect leads to an increase in the risk of diseases. In the resistance phase, an excess of stress is harmful to the body due to the excessive biological cost, and therefore of wear that it induces. The first cause of all pathologies is therefore the individual's incapability of stress response management in duration and/or intensity.

The intensity of the stress depends on the perception of the environment by our external sensors, regardless of the reality of the threat. In the psychological field, sensors determine a representation of the world, which is how the brain adjusts to a constant flow of information. During its interaction with the world, the brain adjusts itself using a predictive probabilistic mode of operation. The idea that the world exists serves as a basis to action and the latter is regulated according to the expected results. So, climbing a staircase where all the steps are equal height, except for one, causes falls because of the broken regularity, and therefore a mismatch of action and the environment. This anticipation encompasses all our fields of perception, as routine is the norm. Stress, which is the organism's biological response, occurs as soon as the sensors connecting the individual to the world detect a change.

Finally, the level of stress impacts the manner in which the brain "appreciates" the environment. This effect is directly related to stress hormones in the brain. Cognitive functions are reached on the basis that they rely on cerebral territories that are vulnerable to these biological modifications. The synchronic impact between stress and action has implications on the way in which performances are developed, and the way in which different memories (e.g., implicit or explicit memory, long-term memory, or working memory) are shaped during encounters. Any increase that would touch the manner in which stress is perceived would have a direct impact on these psycho-cognitive functions. Beyond this it is susceptible to having deleterious consequences on

active learning (learning, consolidation, and recovery) and also on the acquisition of strategies for confronting a crisis situation where safety is threatened.

Mindfulness and Stress Factors and Reactions

Mindfulness characterizes the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding experience moment by moment (Kabat-Zinn 1994). Mindfulness disposition (MD) has been conceptualized as a kind of trait (Kilpatrick et al. 2011; Grossman et al. 2004; Lutz et al. 2015), the ability to be mindful in everyday life, regardless of events and stably in time. These are stable interindividual differences in the propensity to pay attention and to project one's consciousness into the present moment (Chiesa and Serretti 2009). Mindfulness practice, which very often is based on mindfulness meditation (MM), relies on training the mind to sustain attention on body experience, primarily breathing, and deliberately returning attention to it whenever distracted (Smith and Novak 2004; Lutz et al. 2015).

The mindfulness functioning that is developed in MD or after a MM program, is mainly represented by its two dimensions of acceptance and presence. Both were proposed as factors that activate individual resources. Acceptance consists of accepting inner events such as emotions, thoughts, or beliefs when one feels them (Hayes and Feldman 2004). Acceptance does not mean resignation but rather perceiving one's own experience through an attitude of acknowledging the experience rather than judging it as either good or bad. Presence is the feeling of being present in the moment; it refers to the degree to which a subject is grounded in awareness itself. Although empirical research has mainly operationalized mindfulness as a unidimensional construct based on the presence facet of mindfulness, the process of shedding further light on the differential roles of presence and acceptance for individuals' attitudinal and behavioral outcomes would contribute to disentangling the processes through which mindfulness impacts individuals' health, well-being, and behavior (Kohls et al. 2009; Liang et al. 2018).

Whatever MD or MM, being mindful would improve the quality of the subject's relationship with her or himself and the world. Indeed, it increases the perception of the environment, the self and the emotions (Bishop et al. 2004). In doing so, it interrupts automatic affective responses, such as ruminations, and allows for a decrease in their intensity and duration (Stein et al. 2008). Being mindful generates a detachment of the subject, allowing a regulation of the affective experience. Recent data suggest that mindful subjects have an increased ability to cope (coping) with affective experiences compared to control subjects (Weinstein et al. 2009). Mindfulness increases behavioral flexibility (Bishop et al. 2004). Mindfulness would thus provide subjects practicing it with an increased number of adapted emotional response strategies (Weinstein et al. 2009). In addition, mindfulness improves scores in situations of attentional conflict, and this with less anxiety (Tang et al. 2007).

Although studies are few, it seems that subjects considered "mindful" have particular physiological characteristics in many respects. These changes can be observed at rest but more frequently when the subject is active and confronts the world. Mindful subjects show better regulation of cortisol levels (Bormann et al. 2009; Matousek et al. 2010). This is reflected in a more rapid decrease in cortisol levels after the morning peak and a slightly higher level of nocturnal cortisol at bedtime than when they get up (Urry et al. 2006). This better regulation is contemporaneous with activation of the prefrontal cortex and amygdala inhibition (Urry et al. 2006), thus corresponding to inhibition of stress pathways (Matousek et al. 2010). For instance, students subjected to mental computational stress show a lower elevation of cortisol if they have practiced meditation exercises (Integrative Body-Mental Training; Tang et al. 2007). Parasympathetic tone is increased in subjects practicing Mindfulness whether during meditation exercises or in the face of stress (Ditto et al. 2006). A similar observation is made for other types of meditation (Tang et al. 2009).

Altogether, data show that mindfulness works. However, the answer to the question "How does

mindfulness work?" remains on the frontier of science. Mechanisms through which mindfulness may work focus on the conscious access of information. Based on neuroimaging, behavioral and self-report evidences, the Hözel's model describes four main cognitive mechanisms through which mindfulness works: (i) the self-regulation of attention, (ii) change in perspective on the self, (iii) body-awareness enhancement, and (iv) emotional regulation improvement (Hözel et al. 2011). Furthermore, a refined model has been proposed based on the event-related potential review (Verdonk et al. 2020). It articulates those four mechanisms with respect to each other suggesting that (i) mindfulness decreases the threshold of conscious access according to attentional mechanisms ("self-regulation of attention" in Hözel's model), and (ii) mindfulness facilitates conscious process of information that comes from inside (body-awareness and self-awareness) or outside (world-awareness). Mindfulness mechanisms of "body-awareness enhancement" and "change in perspective on the self" from the Hözel's model may result from the facilitated conscious process of inside information, and "emotional regulation improvement" from the facilitated conscious process of self-awareness and world-awareness (Verdonk et al. 2020). Altogether, the literature suggests that mindfulness shapes the psyche, the thoughts, and the body.

Mindfulness and Enactive Response to Environmental Changes

Each confrontation, with its successes and failures, will modify the way an organism operates (e.g., memory) and will weigh on the manner in which the subsequent confrontation will be handled. Integrated over time this dynamic evolution of interaction between the individual and the world eventually defines the health condition that then becomes the ultimate criteria of the effectiveness of the individual's adjustment. It is therefore obvious that any modification of this interactive modification by an enhancement has no impact on just the particular moment but potentially on the possibility of the individual's

evolution. Based on this enactive interaction, we would suggest that being mindful implies singular adaptation for both the perception of the present environment and the understanding of the situation, and decision making in conflicting situations.

The Perception Process and Its Biases

The information processing system is perceived in the form of a chain of transformations that operate in stages and use the subject's knowledge. The processes involved use the perception of information from the environment to adjust the necessary response, notably in a tactical situation. The perceptive process uses a double intake of information; cognitive and emotional. This dual perception is a key element of adaptation to a situation that contributes to understanding the situation and the resulting decisions made.

On one hand, the cognitive perception of information from the environment aims at creating a mental map from which a situational awareness emerges to support the action. This mental map will be all the more difficult to build for a subject if the information that is available to him/her is sketchy, abstract, and/or fragmented. The emergence of mind maps underpins the perception of the environment. This involves many processes including: (i) perception of purely cognitive information (the "what" and the "where"), (ii) updates of the mental map at each moment (here and now), (iii) categorizing information and regrouping what is similar by perceptual habits or by what is new, (iv) the level of awareness of information that depends on another attentional focus and potential conflict on another piece of information already perceived; (v) information detection threshold that depends not only on mental charge and a degree of attention, but also on detection training and the emotional state of that moment (an emotion during a sub-threshold infraliminary stimulus modifies behavior without the subject realizing). It is all of these mechanisms that participate in perceiving the environment. It cannot be envisaged to think of the increase of one of the perceptual mechanisms in isolation from the dynamics that connect them all together. The enhancement is thus *de facto* of information

classification in relation to the subjects' information processing habits.

On the other hand, all perception is evaluated and generates an emotional response. Perceiving a situation is partly recognizing a subunit that we identify in a complex environment. The perceiving subject starts by separating from the known, habitual, and the new. The known comes with a greedy emotional safety and a new feeling of unease that can render the perception slightly aversive. Given the perception of something new, we must consider that a continuum exists that swings from the propensity to explore to the propensity to not explore. Depending on the subject's position, the perception of the information deemed relevant and the resulting treatment will be different. On the other hand, perceiving a situation also means perceiving the emotional dynamics that accompany the situation. This emotional tone is calculated by the subject according to his/her propensity to perceive emotions within his/her environment. It depends in particular on the quality of the social cognition of the subject which implies the dimensions of empathy and theory of mind. It also depends on how the situation is presented to the subject, especially visually; the emotional tone of a visual scene captures the attention even if it is in the periphery of the field of vision or if it is degraded. The emotional distinction of the visual environment aims to alert the individual to an event within his/her potentially beneficent or threatening environment, and divert his/her gaze in the direction of this stimulation to optimally respond to it. This matter raises the point that the negative emotions and stress that are associated are a major factor of determination of what the subject perceives where he/she is given to perceive it.

The cognitive and emotional perception of information is then disturbed by perceptual bias. For example, an emotional state of fear results in early brain activations that occur before the conscious emergence of emotional feeling, and at the perceptual level through a bias of perception of threatening information, to the detriment of any other information present in the environment. Moreover, activating the system wake-up is treated as being strongly involved in perception

quality. It would allow simultaneous attentional orientation toward the threatening stimulus for its preferential selection, and priority access to a deeper, more controlled, and conscious cognitive treatment of the environmental elements. Furthermore, data of affective neuroscience in the visual perception of emotional images show that mood changes the manner in which an individual perceives the world (Wyczesany et al. 2018). Therefore, an anxious mood makes it difficult to disengage emotional visual information (Singer et al. 2012), while a sad mood advocates perceptual avoidance of sad situations (Durbin et al. 2020).

Perception is therefore a function that is not objectively driven, but is rather subjectively and unconsciously driven by emotions. Beyond the complexity of the information, perception mostly relies on emotional bias. Stress, via associated emotional responses, modulates awareness and information awareness. Updating the mental map continuously depends on the quality of this stress regulation.

Mindfulness and Perception of the Present Environment

Being mindful is characterized by the quality of the relationship between the self and the world, and has mechanisms for regulating emotional biases. Attentional capabilities enable the individual to be receptive to any experiences available to him or her. A nonjudgmental attitude enables the detection of biases and reduction of automatic affective responses. This would promote the emergence of an objective point of view on the current situation, in other words enabling detection of a pertinent signal in all the noise of cognitive and emotional stimuli.

A recent study suggests that MM and MD have not the same impact on the quality of visual perception (Kumari et al. 2017). Whereas MM seems to improve the control we have over our eyes, MD was not associated with such control. For example, subjects after a MM were associated with fewer sudden jerky eye movements (saccades) during the tracking of a target, suggesting the eyes were locked onto each target more effectively compared to subjects high in MD. Authors

suggest that it is probably because of the well-illustrated beneficial MM effects on attentional systems (Kumari et al. 2017). Such benefits were not observed in naive MD.

In line, MM is associated with neurophysiological changes indicative of greater cognitive and physiological flexibility (Deepeshwar et al. 2015; Malinowski 2013). It has been showed that such a cognitive training increases flexibility in visual processing because it would reduce the automatic and habitual use of categories in favor of a resampling based on new information (Hodgins and Adair 2010; Moore and Malinowski 2009). On one hand, such an improvement could reduce the detrimental cognitive processing responsible for social discrimination (Lueke and Gibson 2014). On the other hand, it could be helpful for good prediction when the environment is complex and generates uncertainty, for example high-risk situations or missions for high-risk occupation. High-risk occupations present unique challenges due to increased levels of danger and exposure of workers to different types of stress. These include military, police, and firefighters.

Mindfulness and Understanding the Situation for Decision Making

Understanding a situation involves (i) perpetual awareness of the environmental elements in a time and space volume; (ii) understanding their significations, and (iii) anticipation of their future evolution. This description is part of a computational neurosciences' approach that states that a human being is comparable to a probabilistic or "Bayesian" machine. The idea is that our brain would constantly manipulate hypothesis and make calculations that involve a certain degree of confidence to take decisions. To predict the environment and act in relation to these predictions, it seems that the brain takes into account; (i) the uncertainty associated with the signals it receives to integrate them in an (almost) optimal way, and (ii) certain knowledge that is continuously updated. The quality of understanding the situation uses the quality of the prediction as a natural lever for its improvement, and the

regulation mechanisms of cognitive and emotional biases as the relevant targets.

Decision making is basically answering the two following questions: “What are we going to do?” (What?), and “How are we going to do it?” (How?). Making a decision involves choosing between several possibilities in an uncertain universe, within a time frame deemed desirable and possible and making the best use of the available information and resources. Individually and as a group, a decision is an act that engages the person and organization. Decision making can result in a simple or complex action, opinion choice, or action inhibition. It has an adaptive goal, despite the fact that the subject always takes into account the situation. In particular, the evaluation of the outcome of the decision depends on the environment in which it takes place, and on the knowledge/control of the consequences of the chosen action and the one who evaluates it. Furthermore, the way in which people approach the world, and interact with it, represents a true subclinical trait whose impact on decision making is a preferential orientation toward safe or high-risk choices. While the majority of people favor the safe aspect with some incursions toward high risk, few people systematically favor safety or high risk, the level of anxiety tipping the balance toward reduced or increased risk-taking. From a neurobiological point of view, it can be explained by the functional quality of the ventromedial prefrontal cortex involved in self-perception (Damasio 1994).

The interest in the track of mindfulness functioning to optimize decision making is based on data from the literature highlighting its benefit in the different stages of the decision making process: (i) The mindful subject would better detect discordant situations; his or her ability to detect weak signals from the environment is improved and it has been proposed that emotions, and the physiological modifications that result from them, especially in response to situations of moral conflict are better detected (Schofield et al. 2015), (ii) Since the mindful subject is described as having an increased capacity for openness and creativity, he or she is more likely to find appropriate solutions, even outside the box (Ruedy and Schweitzer 2010), (iii) The mindful subject

would be less intolerant of the uncertainty generated by an uncertain situation (Ruedy and Schweitzer 2010), (iv) Finally, he or she is considered to be less prone to risk-taking (Upton 2017).

Conclusions

Stress is inseparable from operational life, but its consequences on high-level cognition can be disastrous. Mindfulness makes possible adaptive responses for a better adaptation in relation with the challenges from life. The puzzle of arguments from literature suggests that the improvement associated with mindfulness functioning constitutes an ecological enhancement, which could be useful for everybody. Furthermore, it could be relevant for high-risk professionals, which have to deal with many challenges from the volatility, uncertainty, complexity, and ambiguity (VUCA) of their professional environment. Finally, it could help to cope with the context of the Covid-pandemic, which is a VUCA environment of life.

Technology (SLATE), University of Bergen,
Bergen, Norway

Abstract

This entry focuses on the relationship between mobility and possibility and postulates that movement – physical and psychological – underpins the possible and its exploration in individuals and in society. This basic argument is supported by a brief examination of objects and inventions on the move throughout prehistory, the circulation of ideas in past and present societies, the mobility of people within and between national boundaries, and the movements of the mind, expressed as episodes of daydreaming and imagination. In each case, potential and actualized forms of mobility

support the expression of possibility-expanding phenomena such as creativity and innovation. But this relation is neither linear nor easy to unpack. Less mobile lives can be lived very creatively, just as constant travelling can be disempowering and reduce one's agency. Final reflections are offered on the interplay between (im)possibility and (im)mobility and the way it shapes human existence.

Keywords

Movement · New mobilities · Creativity ·
Imagination · Innovation · Migration ·
Diffusion

Introduction

Everything in the universe is mobile. We have known this from at least the time of Heraclitus of Ephesus, 500 years before the common era, who famously claimed that “everything flows” (*Panta rhei*). Movement defines the existence of galaxies, as well as that of the smallest subatomic particles. Life itself is intrinsically mobile. By moving around, infants learn about the world and adults can play multiple roles in ever-changing, dynamic societies. Of course, the meaning of movement here varies. Galaxies, infants, and societies move with different rhythms, at different scales, and for different “reasons.” But, essentially, they all change position, in space and time, in ways that describe trajectories and make up evolving networks. By acknowledging and studying mobility, we can thus understand something essential about ourselves and the world we live in. And yet, our view of the world (and the way we talk about it) is often trapped by stable, static, or unchanging units and entities; in mobilities research, on the contrary, we get to see all these entities as they emerge, transform, and dissolve in and through movement.

This entry focuses on human forms of mobility, both individual and societal. Two of the characteristics of this kind of mobility are purposefulness and meaningfulness. In other words, human beings develop intentions to move (or stay) and construct all sorts of conceptions, images, and

visions of what this movement will be like and how it will end. They ascribe meaning to their mobility, acts that can be then related to as good or bad, exciting or scary, useful or pointless. And, with this, immobility also gains signification. It can be frustrating to have your movements reduced, and this is why many societies, across time, used imprisonment as punishment. And there are few things more unsettling and traumatic for human beings than going through forced displacement or migration. But it can also be comforting to stand still for a while, to be grounded somewhere, and to feel at home.

If we see the world, social and psychological, through the lens of movement and mobility, we get to understand better the development of the self, the way our cognition functions, the role of imagination and emotion, and the directions taken by history and social change. But we also get to recognize something more essential about our human existence, ultimately defined by its openness to the future and to other ways of being. And that is the basic fact that *mobility begets possibility*. It is by moving – physically and/or imaginatively – that we experience more of our world and we develop a sense for what is possible as well as explore the wide range of possibilities and impossibilities that distinguishes us from other species.

And yet, this relation between mobility and possibility is not linear or deterministic. It doesn't mean that more mobility will lead to more possibility, manifested, for example, in increased levels of creativity and innovation. Sometimes, constant movement can be distracting or overwhelming. Immanuel Kant is famed, for instance, for never having left his hometown of Königsberg, and still he opened up possibilities for thinking that survive the ages. Stephen Hawking spent most of his life paralyzed, and yet this didn't prevent him from making exceptional contributions to our knowledge of the cosmos. Conversely, many people feel the need for some quiet time alone in order to create. J. K. Rowling sat writing many of her novels in the same café, overlooking the Edinburgh castle. Does this make, though, Kant, Hawking, and Rowling immobile? Certainly not. But it does call to our attention the fact that there is more to movement than physical journeys and

migration. Just like there is more to possibility than writing novels, creating theories, or philosophizing about humanity. Conceptual clarity is called for in both mobilities and possibility studies.

In this entry, I will support and nuance the claim that possibility is born out of and depends on mobility by considering, in turn, the movement of objects, ideas, people, and minds (for a more detailed discussion, see Glăveanu 2020). These forms of mobility are intrinsically connected to one another. Objects don't emerge out of nowhere, ideas depend on minds, and the bodies of people should not be separated from either in a Cartesian way. By analytically making these distinctions, I am hoping here to relate the discussion of mobility and possibility with that of temporality. Each one of these movements captures a different timescale, from phylogenetic and sociogenetic to ontogenetic and finally microgenetic. In the end, it is important to reflect on the notions of immobility and impossibility. Is the impossible defined by an absolute lack of movement? And is the latter even possible?

New Mobilities

New mobilities is a paradigm that emerged in the early 2000s in sociology and related disciplines such as geography, archaeology, and anthropology, as a response to static and entity-based theories of society and culture (although some would disagree with referring to mobilities as a 'paradigm'; see Randell 2018). John Urry, one of its main proponents, aimed to recreate sociology as a discipline that "examines the diverse mobilities of peoples, objects, images, information and wastes; and of the complex interdependencies between, and social consequences of, these diverse mobilities" (Urry 2000, p. 1). He challenged views of society as self-contained, bounded, and unitary and, instead, proposed that it should be conceived in terms of flows, networks, and "scapes." This dynamic vocabulary goes a long way in transforming our conception not only of society but also of culture, globalization, the environment, and the self. After all, living in the hyper-

connected and mobile world of the twenty-first century invites us to reconsider our models as well as everyday practices.

The meaning of mobility in new mobilities – called “new” in recognition of the fact that mobilities have been studied for decades by various disciplines – is expanded to incorporate dimensions that cut across the psychological, physical, social, economic, and political:

1. “the corporeal travel of people for work, leisure, family life, pleasure, migration and escape, organised in terms of contrasting time-space patterns ranging from daily commuting to once-in-a-lifetime exile;
2. the physical movement of objects include food and water to producers, consumers and retailers; as well as the sending and receiving of presents and souvenirs;
3. the imaginative travel effected through the images of places and peoples appearing on and moving across multiple print and visual media and which then construct and reconstruct visions of place, travel and consumption;
4. virtual travel often in real time transcending geographical and social distance and forming and reforming multiple communities at-a-distance;
5. communicative travel through person-to-person messages via personal messages, postcards, texts, letters, telegraph, telephone, fax and mobile” (Urry 2007, p. 47).

This wide scope is welcomed as it both highlights the relevance of mobilities studies nowadays and the necessarily interdisciplinary nature of this endeavor. And yet, beyond cataloguing types of movement and studying them in detail, it is also important to develop a deeper reflection on what mobility *does* to our existence and the many ways, positive and negative, in which we are transformed by it. New mobilities scholars are right when it comes to not romanticizing movement and exploring, for example, the “darker” sides of mobility as well, including in terms of oppression, environmental destruction, or increased inequalities (see Ohnmacht et al. 2009; Macková and Kysučan 2016). But how exactly does mobility operate? What are the differences and similarities between the movements of bodies and information, for instance? What about the difference between human and non-human mobilities, more broadly?

There are many conceptual questions still to be raised within new mobilities. Fortunately, the methodological developments inspired by this emerging paradigm have been substantial and allow us to capture previously invisible or understudied phenomena. The specific methods used by researcher include, but are not reduced to:

- “the ‘observation’ of people’s movement, of bodies strolling, driving, leaning, running, climbing, lying on the ground, or (...) visiting a petrol station. This involves observing directly or in digitally enhanced forms mobile bodies undergoing various performances of travel, work, and play. (...)”
- Second, there are several emerging forms of ‘mobile ethnography’, which involve participation in patterns of movement while conducting ethnographic research. (...)
- Third, there is the keeping of ‘time – space diaries’, in which respondents record what they were doing and where, and how they moved during those periods. (...)
- Fourth, there are varied methods of ‘cyber-research’ that explore the imaginative and virtual mobilities of people via their websites, multi-user discussion groups or listserves, as well as through the use of computer simulations. (...)
- Fifth, there is imaginative travel normally involving experiencing or anticipating in one’s imagination the ‘atmosphere of place’. (...)
- Sixth, much travel and communication involve the active development and performances of ‘memory’. This necessitates research methods that simulate the active employment of photographs, letters, images, souvenirs, and objects. (...)
- Seventh, much mobilities research will need to examine multiple ‘transfer points’ (...), ‘places of in-between-ness’ involved in being mobile but immobilised in lounges, waiting rooms, cafés, amusement arcades, parks, hotels, airports, stations, motels, harbours.” (Sheller and Urry 2006, pp. 217–219)

The new fieldworks mentioned above should all be of interest to scholars working on possibility studies from across different disciplines. They each reveal something interesting, above all, about the interplay between the possible and the impossible within mobile societies and mobile lives. What remains to be theorized and studied further is precisely this articulation between (im)-possibility and (im)mobility in the case of objects, ideas, people, and minds.

Objects on the Move

One of the most directly observable mobilities is that of objects. As people and ideas move around, they usually leave material traces in the forms of things and institutions. These embody the views, knowledge, and norms of different communities, and, as such, their presence in faraway places is taken as a marker of cultural contact. And one of cultural transformation, given that the objects that “travel” most and furthest are innovations.

In fact, the prehistory of humanity is defined by vast migrations and the circulation of early technological inventions. These prehistoric tools expanded the sphere of the possible for entire groups that, through travel and exchanges, got to spread these innovations and to improve and transmit them forward. The likelihood of these processes taking place depended on demographic factors. If useful inventions were rare, then small and isolated societies had small chances of developing them and, even if they were created, the risk of losing them, because of random events or incomplete transmission, was great (Richerson et al. 2009). As people migrated and communities became larger, technological invention and its transmission increased, what Richerson and colleagues called a “population-technology-population positive feedback”:

“We can assume that the first hominins, like our closest relatives, the chimpanzees and bonobos, lived in social groups knit by intense interactions among group members. At some point, their social lives began to expand far beyond the local group. Hominins first began to systematically exploit large animals as food sources, whether by hunting or scavenging, around 2.5 mya (reviewed by Plummer 2004; but see McPherron et al. 2010 for possible evidence of even earlier forays into carnivory). (...) Anatomical evidence from later *Homo ergaster/erectus* (after 1.8 my) suggests an adaptation to a high level of mobility, particularly long-distance running (Bramble and Lieberman 2004). Both of these behavioural trends are linked with well-recognised technological developments. The first widespread evidence of carnivory around 2.5 my is of course associated with the earliest stone tools (Plummer 2004; de la Torre 2011). (...) There may be basic functional explanations for both the first development of stone tools and the subsequent shift to bifacial shaping of artefacts. However, the dispersal of these new behaviours across large parts of

the African continent, and eventually into Eurasia, required at least some exchange of information among local populations.” (Kuhn 2012, pp. 76–77)

The same deep connections between mobility and innovation, as illustrated by the movement and transformation of objects, have been documented for later prehistory (e.g., Knappett and Kiriati 2016) up to the early modern period (e.g., Schilling 1983). In the latter, for instance, the forced migration of Calvinist communities from the southern Netherlands in the sixteenth century had a great impact on the economic modernization of host societies in Western Europe and, in the long term, the emergence of modern capitalism. The objects travelling in these cases are much more complex and include an important symbolic dimension that brings them close to the circulation of ideas. But it is always the case that, throughout history, objects and ideas are connected by processes of creativity and reflect the cultural conditions and life experiences of their makers. Without a physical or material expression, however, the “durability” of ideas, knowledge, and values would be considerably reduced and, without acts of mobility and position exchange, the creation and transformation of objects, in the first place, would become all but impossible.

Ideas on the Move

As people and things travel, so do their conceptions and views of the world. All innovations, especially successful ones, operate at two different levels: on the one hand, there is the level of practical action where innovations become tools to operate with; on the other hand, they explicitly or implicitly bring new ideas that either consolidate or change the direction a society is moving in. And this is precisely why ideas on the move are so powerful – they are the root of changing mentalities, social practices, and social movements. Then, how exactly do ideas “move”? The migration of people is again essential, but so are general processes of communication between them. Today, the latter are greatly facilitated by the use of technology and social media platforms. In

theory, more becomes possible for people who are exposed to the views of others. In practice though, the phenomenon of information bubbles and the circulation of misinformation radically reduce possibilities for change.

The circulation of ideas is explained in science primarily with the help of diffusionist theories and models. These assume that cultures are dynamic and that innovations that travel don't just add themselves to a local culture but shape it. Diffusion patterns include, among others, "a partial penetration of two cultures, the overlapping of a 'weaker' culture by a 'stronger' one, the parallel mixing of almost all cultural aspects, or only sporadic adoptions" (Heitz and Stapfer 2017, p. 15). The focus on the diffusion of ideas started in disciplines like geography and anthropology from the late eighteenth century onwards. And it led to a transformation of how we understand culture, society, and contemporary phenomena:

"'Migration of ideas' opens up a vast field of study—how Indian and Arabic knowledge reached Medieval Europe; how Christianity, hand-in-hand with colonization, spread across the globe; how Marxism spread and adapted to different conditions; how technical innovations and scientific discoveries spread and get taken up in different contexts; how conquerors force their views and practices on the conquered; more recently how global capitalism and 'McDonaldisim' has resulted in a depressing homogeneity around the world and so on." (Porter and Poerwandari 2008, p. 64)

It would seem, from the above, that diffusionist models ultimately explain the spread of impossibility, for instance, the impossibility of imagining a different way of living in society. Dominant ideas and practices circulate, taking over local cultures and spreading uniformity rather than diversity. And, given that possibility resides in difference (Glăveanu *in press*), ideas on the move can easily close down rather than open up new spaces for human thinking and action. And yet, it is important to note here that ideas never "travel" unchanged. The process of transmission and diffusion is equally one of *transformation*.

This is acknowledged to various degrees by different theorists of diffusion. Gabriel Tarde (1962) built a new sociology on the premise that society is made up of invention and imitation, and,

while he recognized that imitation often means adapting ideas, he nevertheless outlined different laws for these two phenomena. Everett Rogers (2003) famously offered a generalized model of diffusion including the S-shaped curve of adoption of innovation over time; however, his focus was again never on reinvention through transmission, but on how innovations are adopted as such and passed on. Psychological accounts drawing on parallels with biology, such as Dawkins's (1976) meme theory and especially Sperber's (1996) epidemiology of representations, left more room for the role of interaction and communication between people. But it is early sociocultural accounts of transmission, like the one formulated by Frederic Bartlett (1923), that fully recognized the constructive nature of ideas on the move. This became the premise of more theories, such as social representation theory (see Moscovici 2001), and a new literature on mobility and intergroup contact as sources of creativity, innovation, and possibility in society.

People on the Move

Historically, the mobility of objects and ideas was based on the movement of people. Nowadays, however, makers and buyers of a product will rarely meet, even if the relation is still enabled by human intermediaries. The circulation of ideas online makes it possible for individuals to connect with each other from the comfort of their own homes. Exchanging with someone at the other end of the world can be done in an instant and take little physical movement except for typing messages on a keyboard. And, with these exchanges, there is an assumption that users could become more open, flexible, and even creative. This hope that people's mobility leads to more creativity, innovation, and, ultimately, prosperity underlines the European Union's four freedoms of movement – of goods, capital, services, and labor. The last one, the movement of people, however, consistently comes under criticism from right-wing, populist governments ready to blame national problems on "outsiders" and demonstrably fuelled the UK's exit from the Union.

And yet, the movement of people shouldn't be reduced to the act of crossing national boundaries. Not only is migration taking place primarily within countries, but our daily life is marked by the longer and smaller journeys we take and even by micro-mobilities within the house. At the moment of writing, almost half of the world's population has been under different forms of lockdown, and exit strategies are gradually set in place; still, constraints on personal mobility abound. But this doesn't mean that everyone is immobile, standing still or has been so for months. The notion of personal mobility should thus be extended to incorporate immigration, online activities, and everything in between:

"Personal mobilities constitute self-propelled movements, which include, first, the natural corporeal (physical) non-technological self-moving, more simply known as walking, and obviously those physical mobilities extended by technologies (driving automobiles and bicycling and motorcycling). Personal mobilities further include virtual mobilities through fixed and mobile telephones and the Internet. Self-propelled mobilities exclude, by their very nature, the use of public transportation and communications, in which movements are mediated, though comparisons between automobiles, on the one hand, and buses and trains, on the other, as well as between telephones versus telegraph and postal services, have been made, and some will be made later on." (Kellerman 2006, p. 2)

The important question for this entry is *how* personal mobilities contribute to personal possibilities. It is undeniable that living mobile lives contributes to our imagination and creativity by (a) helping individuals acquire multiple experiences of and perspectives on the world; (b) increasing the chances of meeting others and exchanging ideas and objects; and (c) expanding our agency and sense of what is possible in our lives. In making these observations, however, we need to recognize the fact that there is no linear relationship between mobility and possibility. More travel and more experiences don't necessarily translate into more creativity, especially if they come out of forced displacement or subject the person to traumatic events. Interestingly, it is the capacity to imagine that is directly affected by

trauma, and yet, healing resides precisely in exercising this capacity and being able to envision a new and different future (Womersley 2020). In these cases, the experience of migration can become one of impossibility. On the other hand, sedentary people can be highly creative, whenever they diversify their experience and interactions with others from the more stable positions they occupy in the world.

There is a growing literature today on the relationship between migration and the imagination (Salazar 2011), as well as empowerment (Trifanescu 2015). The risk here is developing a romanticized perspective on movement. There are many variables, personal, social, economic, political, and historical, that mediate the connection between migration and possibility and determine its concrete outcomes. But there is little doubt that lives lived in forced immobility and the absence of social contact are closed to the possible in the sense of lacking opportunities to envision alternatives (by considering the views of others) and choose between them (by guiding one's own course of motion and action). To understand why, we need to turn our attention towards a final key dimension: the psychological one.

Minds on the Move

All human mobilities, individual and collective, have a psychological component to them. They are triggered by needs and visions of the journey and its end point, accompanied by emotions and the motivation to continue (or to stop), and depend on the psychological adaptation to (and transformation of) one's new life at the destination. Minds and bodies travel together as an inseparable unit given that all our mental processes are embodied (including imagination and affect) and our entire psychology depends on movement. It is not without reason that cognitive development, for example, starts from the sensorimotor stage (Piaget 1950), or the emergence of a human self depends on our capacity to "move" to the position of the other, at first physically and then mentally (Mead 1934).

There are, thus, complex relations between psychological explorations of the possible and mobility that don't depend on migration or even bodily movement. The mind itself "travels," through daydreaming and the imagination, to other temporalities (e.g., the imagined past, the projected future), geographies (e.g., faraway places, including ones impossible to visit), and spheres of experience (e.g., moving between home, school, and work). Zittoun and Gillespie (2015) formulated a theory of imagination premised on psychological forms of mobility that they describe as the "loop model." According to them, imagination loops in and out of immediate or proximal experiences of the here and now and into distal experiences. This conception builds on a sociocultural psychology grounded in movement, for which the possibility of being in different positions and diversifying experiences is essential (see Gillespie and Zittoun 2013). While recognizing the importance of repositioning, trajectories, and transitions for human existence, the authors posit too sharp a differentiation between minds and bodies and proximal and distal experiences and thus create the risk of harmful dichotomies (e.g., in our case, that between physical or embodied movement, on the one hand, and psychological or imaginative loops on the other).

The reality of psychological mobilities is that they are mental and physical *at once* and that possibility-expanding phenomena such as imagination and creativity don't "take us out" of the here and now but, rather, bring the "then and there" into it, transforming the experience of the person (see Glăveanu et al. 2017). In the end, our engagement with the possible depends *both* on mind and body and, beyond them, on a physical and cultural environment populated by objects and by other people. My own work has been dedicated primarily to understanding the role of others – and differences with them – for creative action and possibility (for more details, see Glăveanu *in press*). From this standpoint, psychological mobilities are rooted in physical ones, and explorations of what is possible and impossible depend on the two. There is no human movement

that doesn't trigger and result in emotions, needs, thoughts, and anticipations of the future. And the processes that help us engage with this future equally invite and depend on mobility.

Concluding Thoughts

In this entry, I made the claim that possibility originates in mobility (see Glăveanu 2020) and that, in order to grasp this, we need a complex understanding of both phenomena. Mobility, for example, isn't reduced to the migration of people but captures, more broadly, the movement of things, ideas, and human experiences through offline and virtual environments. At the same time, possibility shouldn't be reduced to revolutionary creations and historical inventions. All mundane acts of anticipation, imagination, creativity, wonder, awe, and serendipity (and many others, as illustrated in this encyclopedia) contribute to making us aware of what is possible and help us explore potentialities and actualize at least some of them, allowing new cycles of mobility and possibility to take place.

Towards the end, I want to reflect for a moment on what looks like the reverse of these notions: the *impossible* and the *immobile*. To start with *impossibility*, it is physically impossible for an entity in our universe to be perfectly still, just like it is for a living system to not express any kind of movement. For human beings, for as restrictive as their material conditions might be, for example, in prison or in situations of being physically immobilized, there is always the possibility of psychologically reaching out to new spheres of experience. Of course, these are extreme examples and, most often, we live lives somewhere on the continuum between (im)mobility and (im)possibility. But if the basic premise outlined here is correct, then ontologically we need mobility in order to exist as beings within the realm of the possible (Glăveanu 2018), open to difference, to otherness, and to unknown futures. Absolute impossibility comes from no movement or even no the prospect of it – when people feel stuck, trapped, and unable to "move on." A perceived

lack of agency leads, in these cases, to either hopelessness or anger. In societies that appear paralyzed by inequality, plagued by misinformation, and fired up by populism, it is these kinds of experiences that scholars of new mobilities and possibility studies would do well to focus on and understand better.

Myths

Sandra Obradović

School of Psychology and Counselling, The Open University, Milton Keynes, UK

Abstract

The current entry discusses the concept of “myths” and the role it plays in both traditional and contemporary societies. When we think of common sense understandings of myths, we often think of false beliefs or stories that are told that do not necessarily reflect real events, but can become powerful mediators within social, cultural, and political life that can give meaning to the identities, practices, and morals of communities. Their power lies in their continued relevance across generations and societal transformations. Myths are meaningful not through the stories that they reproduce, but through what is achieved in the telling of those stories.

Keywords

Communities · Identity · Morality · Myth · Narrative · Social belonging

Introduction

What is a myth and why should we care about myth as social scientists? This entry aims to answer this question by discussing existing work on myths and mythology, particularly focusing on the functional role they play for binding communities into essential entities, and providing meaningful frameworks for understanding “our” values, norms, and morals through the telling and retelling of certain stories.

The entry is structured in the following way: First, I will outline some common conceptualizations of “myth” within the social sciences, aimed at providing an understanding of what myths are. Second, I will discuss the role myths play for social, cultural, and political communities. This will be followed by a consideration of how

research on myths can be done, drawing on examples from different disciplines. Last, I briefly touch on the possibilities opened up through the narration and continued existence of collective myths before concluding with some remarks on why myths remain alive and powerful in contemporary societies.

What Is a Myth?

The concept of “myth” tends to evoke thoughts of mystical events that extend beyond our immediate and imagined reality, which narrate the origins of different peoples and communities. Myths can be thought of as stories that might or might not be true, but that nevertheless carry with them an important personal, sociological, and cultural meaning. They make the unfamiliar familiar, the complex simple, and the distant past interlinked with the present.

Myths range from the intimate to the public, including personal myths as well as collective ones. In therapeutic contexts, myths have been found to serve a critical function for establishing both a personal and collective identity and belonging, supporting moral values and providing essential meaning in times when the world feels senseless (May 1991). While myths permeate multiple domains of human life, the focus of this entry is primarily on myths that refer to the existence and origin of communities, such as ethnic groups, nations, and political groups, and so, references to “myths” tend to imply collectively held and believed myths.

How do myths differ from other types of cultural stories? What is the difference between myths, legends, folktales, and fables? Folktales and fables can be understood as seasonal and entertaining stories often based on fictitious events, retold in acts of sociability. Legends in contrast, while less fictitious than folktales, tend to lack the persuasive power that myths hold (Lincoln 2014; Malinowski 1926). Last, myths can be understood as a category of stories that are sacred, which become embodied and reproduced through rituals, moral codes, and values, and through the social organization of

human civilization. These stories, unlike folktales, for example, do not persist because they are interesting fictitious narratives, but instead, myths form the backdrop against which reality might be shaped and understood.

Within the social sciences, the earliest influential work on myths comes from the anthropologist Branislav Malinowski (1926). Malinowski, through his studies of preliterate societies, argues that myths form a vital component of human civilizations, as they play an active role in expressing and codifying beliefs and enforcing moral values. Malinowski (1926, p. 12) considers a myth “not an aimless outpouring of vain imaginings, but a hard-working, extremely important cultural force” that is not just a story told within a community, but “a reality lived.” As such, Malinowski considers myths as both embedded within discourse and reproduced through social and cultural practices.

Other authors offer similar definitions of myths that emphasize not the historical accuracy of the stories, but about the possibilities of what might be achieved through their communication. Schöpplin argues that myths are “about perceptions rather than historically validated truths (in so far as these exist at all), about the ways in which communities regard certain propositions as normal and natural and others as perverse and alien” (1997, p. 19). The ability of myths to normalize certain beliefs and practices is echoed by Barthes who sees myths as having “the task of giving an historical intention a natural justification, and making contingency appear eternal.” (2006, p. 268). The emphasis on making the unfamiliar familiar and giving it meaning is also noted in the work of Bottici (2007, p. 13), who similarly explains that myths “provide names through which the unknown first becomes masterable, but they also provide narratives, which by inserting events into a plot, can produce and reproduce significance.”

Taking the above interpretations into consideration, we can see that there are a few key features shared among scholars in what defines a myth. Myths can be understood as types of stories, or histories in narrative form, which are told and transmitted across time and space. Their power

lies not in what is said (or in the ability to retain and reiterate accurately events of the past), but in what is, and might be, possible through references to them. Myths construct and legitimize the possible through social, cultural, and political arrangements, practices, and rituals. They do so through the construction of simple narratives that communicate complex things about human relations, histories and moralities within societies. Last, by traversing time and space and decoupling the narratives from temporalities, myths continue to be as relevant in the present life of a community as they had been in the past. This is why myths become particularly potent in times of sociopolitical change and transition, as will be discussed below.

The Social and Political Function of Myths

Regardless of their historical accuracy, myths are pragmatic. They always serve a particular purpose for those who believe in them and reproduce them (through both discourse and practice). Returning back to Malinowski, he succinctly summarizes the function of myths by explaining that:

Myth fulfils in primitive culture an indispensable function: it expresses, enhances, and codifies belief; it safeguards and enforces morality; it vouches for the efficiency of ritual and contains practical rules for the guidance of man. (1926, p. 19)

As such, myths both narrate events of the past and serve a practical function for understanding the present. By narrating events of the past in certain ways, societies and cultures actively engage in reinforcing a certain world order and moral wisdom. Therefore, it should be noted that myths are not static or fixed, but adaptable to changing circumstances, and used in ways that serve contemporary needs.

A particularly important kind of myth that illustrates this active dimension, explored in the context of nations and their political order, is myths of origin, or foundational myths. In particular, a key focus within this literature has been on understanding how myths of the origin of a nation (or ethnic group) become constructed and

mobilized for political purposes. These types of myths refer to the stories told about epic battles, struggles, or sacrifices that mark the beginning of the historical time of a national group. Their appeal is often emotional and tends to emphasize a sense of historical injustice or victimhood which comes to define the identity of a social group.

What is crucial to keep in mind is that the power of myths comes not from their ability to retell a particular event (or set of events) in an accurate and enticing manner, but rather from their ability to draw links between actions and events of the past, and those of the present. For members of nations for whom a particular foundational myth is salient, it is important to understand not only what is said in narrating the myth, but also what it says about the group, its norms, values, and morals. Given this, myths are often-times used as templates for making sense of changes and uncertainties in the present, as they hold the possibility of becoming guiding lenses through which new challenges are made sense of (Obradović 2019).

Successful myths of origin are those that are able to adapt to changes. In order to do so, these myths must be rooted in historical experiences (or real events) but also be vague enough to mirror the local context and circumstances and so remain relevant across time. In order to survive, myths need to be told and retold, both by institutional forces, but more importantly by social actors. By reproducing myths, social actors also become influenced by the meaning they carry for understanding the history of the group, what political actions become legitimized, and what possible future becomes desirable.

However, while this might serve as a key source of power for myths, it also, according to Zerubavel (1995), can serve as their main point of weakness, because the same historical event, which serves as the foundational myth of a society, holds the possibility of being interpreted by different groups in different ways. Indeed, the same event can be retold by different social groups in contrasting ways, as is exemplified in the retelling of the myth of Masada in Israel (Zerubavel 1995). According to Zerubavel (1995), the multivocality of national myths,

namely their ability to be told in different ways, allows them to stay alive across time, but it can also lead to the emergence of counternarratives, which can challenge the meaning of the myth.

Research on Myths

How do we “do” research on myths, their function as cultural forces, and their ability to provide politics with legitimacy?

A first crucial thing to consider is that myths need to be understood within the context of their existence. If we remove the telling of a myth (as a story) from the context that it exists in, we strip it of the meaning and implications it holds for social and cultural norms and practices. Anyone that reads Malinowski’s (1926) stories from his research will be lost in understanding what these stories mean for the local population without the interpretative lens offered. As such, it is important to study myths in context, and to have extensive enough contextual knowledge to interpret how they become embedded within the social fabric of everyday life. Without this “insider” understanding, we might be unable to grasp what a myth “does,” and only capture what it says, on a semantic level.

Second, there are different ways in which we can study myths and their power. Among anthropologists like Malinowski’s ethnographic work, being deeply embedded within the community, and observing interactions and behaviors of community members, is one avenue to follow to understand how the stories shape the cultural rituals of a particular community. Thus, anthropologists have tended to focus on the existence and power of sacred myths in communities and tribes. More recently, other scholars, particularly those within sociology, political science, and social psychology, have tended to focus on the existence of myths in more complex and modern societies.

An important area of research for this latter group of scholars is centered on myths within the context of nations and their histories. Different terminologies are used within this research, for example, researchers discussing foundational myths, nationalist myths, and political myths. A

nationalist myth, as Bell (2003, p. 75) explains, is “a story that simplifies, dramatizes and selectively narrates the story of a nation’s past and its place in the world.” Nationalist myths are similar to myths of origin, as they tell the story of epic events that became defining for the in-group’s identity, future, and perspective on the world. But they can also be less explicitly rooted in exact events, and instead account for the origin of a people, on a more abstract level. For example, Jovchelovitch’s (2012) research in Brazil shows how foundational myths of the Brazilian people are kept alive in the contemporary public sphere but are used in contradictory and complex ways, to both emphasize negative and positive aspects of the people. For example, she argues that the national myths, which anchor the mixed nature of the “Brazilian” in corruption and impure blood, are also reclaimed and used to celebrate diversity, the positivity of otherness, and to champion positive and bottom-up social regeneration. This study shows how myths become narratives of the origins that permeate temporal boundaries and historical contexts, taking on a variety of forms to adapt to changing circumstances.

Another avenue of research on myths and their functional role in societies is to examine the presence of myths within in political discourse. For example, research on political myths and their ability to legitimize particular political actions is interesting to consider here. Esch (2010) draws on official level texts from the Bush administrations’ “War on Terror” initiative to how political myths (such as that of American Exceptionalism) become utilized to legitimize the post-9/11 policies of the US government and ultimately providing justification for the invasion of Afghanistan in 2001. Her work shows that myths can become embedded in political discourse in ways that allow for history, and the meaning it carries, to be moved from the past to the present, ultimately constructing certain future possible projects as more or less legitimate.

What is interesting to reflect on, in relation to the political myths discussed above, is that the domain of knowledge within which politics play out tends to appeal to knowledge and reason. Rationality becomes a source of legitimacy for

political authority, and other forms of knowledge are seen as less valuable. Yet myths are powerful precisely because they appeal to other forms of knowledge, to human emotions, and to our need to make sense of the world around us. As such, it would be mistaken to believe that myths exist outside our rational thinking. As Della Sala (2010, p. 3) argues, “myth is not necessarily an antithesis to knowledge and reason.” But rather, it serves as a “valuable instrument in determining what is right and what is to be done in governing” (p. 3).

This sentiment is echoed among other scholars of myths and their societal function, who consider the juxtaposition of mythos and logos as problematic and unproductive (Lincoln 1999). Instead of examining the extent to which myths reflect accurately the historical events that they are rooted in, research on myths should (as has predominantly) be focused on what realities become possible, and also what realities become restricted, through the telling and retelling of myths.

What Do Myths Make Possible and What Might Limit the Possibility of Myths?

Myths bind individuals together into communities and nations and, as such, play a role in making possible the existence of social groups as atemporal and essential. By narrating the origin of a group, myths also bind present-day in-group members, to members of the past, and make certain actions in the present more or less desirable (Obradović 2019). In a study conducted in Serbia, examining public ambivalence toward EU integration, it was found that the foundational myth of Serbia (resting on the simultaneous victory and defeat in the Battle of Kosovo) was very much alive in the present through both its links to physical territory as well as psychological identification with the nation. This link was in turn used to support arguments of resistance toward any political change that was threatening to the meaning behind the myth and, by implication, the identity of the nation.

Myths make possible the existence of temporally continuous and essentialized group identities for particular social and political purposes. Myths

make possible the existence of imagined political communities (Anderson 1991). This important force of myths is often seen in times of social turmoil or transformation. The increased social uncertainty and instability that come with change make simple stories appealing, as they offer a blueprint for making familiar the unfamiliar and unknown. Because they remain as lived realities that share the sociocultural values and morals of a group, myths offer reassurance in times of insecurity, instability, and change. Using narratives that carry a moral message, myths, and the histories that are drawn upon, both open up possibilities for the future and, at the same time, limit them.

Yet, with modern societies, modern forms of keeping historical records are possible, an innovation which might potentially limit the power of myths in the future. The existence of objective records of historical events could ensure that inconsistencies between mythical stories and the events they draw on might need to be limited. Another key dimension of society that might challenge the possibility of myths is education. The institutionalization of particular representations of history, and their transmission through education, might make myths into folktales, removing their authority and moral message and instead turning them into entertaining stories told by communities, but lacking the power to shape communities as they had done in the past.

While these innovations, alongside mass and social media, might indeed be posing a challenge for mythologies and their social power, the increasing appeal to history, the rise in nostalgic thinking, and the importance of social cohesion and group belonging, all seem to attest to the continued presence and prevalence of myths within modern societies and social groups. Future research should explore how myths become appropriated and communicated through new mediums, and their mobilizing power.

Conclusion

Myths tend to be equated with false beliefs. Like conspiracy theories, they are seen as alternative versions of reality, rooted in real events but narrated

in ways that challenge rationality and reason. However, myths play a powerful cultural, social, and political role in both premodern and modern societies. As has been discussed in the present entry, myths should be understood as types of stories that exist in contexts that range from tribes (Malinowski 1926) to supranational unions (Della Sala 2010). Myths are stories, they often take a narrative form, and they are told and retold for a particular purpose. As the purpose and need of a community changes, so does the telling of a myth.

This is so not because myths need to represent historical events in an objective and factual manner, but because, in the telling of a mythical story, individuals and communities reproduce certain cultural values, norms, and morals that function to legitimize existing sociopolitical arrangements, practices, and rituals. Myths are important political tools, and they are often mobilized as such, particularly to garner support for political actions. These actions can be aimed at reproducing the status quo, or challenging it. As such, myths make possible the binding of communities of the past, with their actors of the present, and those envisioned leading the group in the future. This interlinking gives crucial meaning to actions, behaviors, and practices of the group.

Myths might be equated with false beliefs, yet their ability to shape possible lived realities makes them as powerful as they have been over preceding centuries and, as such, an important study within the social sciences.

Narrative Therapy

Bridgid Hess
Psychology, Webster University Geneva,
Geneva, Switzerland

Abstract

This chapter will give you an idea of the basic assumptions that narrative therapy makes, some people who have influenced it and its philosophical history. It will also give some practice-based ways of forming and crafting questions using deconstructive language that opens space for alternate stories to be told. Throughout the chapter, I foreground embodied language that is rich in metaphor and lived experience. I have broken with the tradition of giving you theory at the beginning in favor of placing it in a supportive position towards the end. You could equally read the section on its background history and philosophy at the beginning if that makes more sense to you.

Keywords

Social construction · Post-structural philosophy · Deconstruction · Power and knowledge · Culture · Language · Embodied knowledge · Discourse

Introduction

I was drawn to narrative therapy by ways of working that empower people and communities to write their own life stories, returning local knowledge to the center. It moves away from a structuralist top-down approach, where people are understood to have a core identity and problems are surface manifestations of deeper truths that need expert interpretation (White 2000, p. 61). It favors a post-structural approach, where identity is fluid and grows like a rhizome rather than a tap root, like potatoes that grow in communities or clumps and spread underground where identities pop-up where least expected. I have harvested many crops of potatoes as well as identities in this way over the years, picking where I had not sown and reaping through other peoples' wisdom. This allows for multiple possibilities on an ever-evolving landscape of possibility where our actions, along with others, constitute our beliefs and identities (White and Epston 1990). Questions draw people away from an intrapsychic internalized state of being. For example, an internalized question might be, "How does this make you feel?". This focuses on an internal dynamic within a person and assumes a form of depth or core "you" that feels something. We ask questions where the feeling is in relationship to a context, for example, "What does this feeling do to you?"

or “What does this feeling make you think or believe about yourself?” or “What would you call this feeling?”. This form of enquiry opens space to explore a feeling as something that is influencing or affecting a person, like a weather system and always in relationship to a context.

I found myself living and working for many years in Southern Africa where the volatile tides of history were constantly present in the power relationships that were both past and present (Hess 2006). Much of their local knowledge had been overtaken by Western forms of therapy that had focused on the individual autonomous self.

Narrative therapy made sense to me. It moved away from individualist, more western models of psychotherapy and psychopathology, favoring local collective knowledge and the values and intentions that people hold for their lives. It also drew me in through its rich descriptive metaphors. I have found metaphors and stories invaluable when working in a cross-cultural context, where even a language is limited. An example of this was work I did on the mines in South Africa. I would train HIV facilitators (often with little English) for a week on being HIV facilitators. Fact-based learning had not had much impact. I worked with their local knowledge and beliefs. Together we drew pictures of villages, wisdom figures, and what they valued in their communities. We were able then to explore the ways in which HIV worked within their embodied contexts. Many believed HIV was a myth, created by a white man to kill them. They often spoke in their own languages, translating for me as they saw appropriate, which located control more in their hands. I was constantly amazed at how fully engaged they were in the process. Although the odds were stacked against me in my color, gender, language, and history of oppression, there was something in the work that held us on the same page. We were able to explore ways through drawing on boards in which problems have trapped and affected them and how HIV worked in their communities. This gave opportunities for other stories to emerge and for them to be in charge of their own stories. This challenges the modern structuralist notion of pathology that has labelled people as somehow lacking.

Stories Waiting to Be Told

Narrative therapy is, as you might imagine, about how we tell our stories, what we select, and what we consider newsworthy to talk about. Walther and Carey (2009, p. 6) put it this way: “As therapists, we are interested in notions that are supportive of new possibilities and multiple-storied lives. What else might we see or hear in a person’s situation, other than a singular description?”

I was invited some years ago to a church-based group to speak on marriage. They had been listening to an American video series that focused on Western metaphors around a dyadic unit of husband and wife. I asked the question “What are the stories in your families that hold the wisdom and hope for the future?”. This intentional question situated them in their own history and traditions, rather than in some ahistoric linear assumption of what marriage should look like from the dominant view of the church at the time. The conversation turned from passive recipients to co-creators of living stories, moving from heads to living memories. They gave such rich and full descriptions of people who had shaped their lives. Some of their own parents had broken traditional gendered boundaries, in order to help carry water or care for children. These are the stories waiting to be told, stories that challenge some of the unexamined assumptions we make about how life should look. These stories also contradicted much of the dominant gender-based violence that goes on in the community, building up different ways of living respectfully in the world. This in turn influences how we speak and make meaning of our lives and takes us on a new trajectory.

Narrative therapists could then be described as helping to critically edit texts that have become taken-for-granted as assumed truth. It has taken much of its wisdom and metaphors from the arts, post-structural philosophy, and discursive practices (a longer discussion of which you will find later in this chapter). Foucault (1988, p. 155) when describing discourse, says “Critique does not consist in saying that things are not good the way they are. It consists in seeing on what type of assumptions, of familiar notions, of established

and unexamined ways of thinking these accepted practices are based.”

The therapist’s position is like an investigative journalist who is intrigued by the twists and turns of the journey. They act as an editor on the person’s own text and are particularly attentive and curious about parts of stories that might have been overlooked when a person focuses on a “problem story.” The assumption is that every story has its weaknesses and every story is context dependent. Morgan (2000, p. 3) says “I sometimes think of the possibilities for the directions of the conversation as if they are roads on a journey. There are many cross-roads, intersections, paths and tracks to choose from. With each step, a new and different cross road or intersection emerges – forward, back, right, left, diagonal, in differing degrees. With each step that I take with the person consulting me, we are opening more possible directions. We can choose where to go and what to leave behind.”

Maps on a Journey

Maps show a migration on a journey that is moving, changing, and evolving. White called this a migration of identity where possibility is constantly evolving into new destinations. He loved maps and just before his unexpected early death in 2008, devoted a whole book to maps of narrative practice. He says “When I was a young boy it was maps that made it possible for me to dream those other worlds up and imaginatively transport myself to other places” (White 2000, p. 3). Walther and Carey (2009, p. 6) develop this idea by make use of Deluze’s concept of “deterritorialisation” or a “line of flight” from the territory that we are experiencing in order to reach a different terrain of life which offers other possibilities.

We select certain “truths” or incidents as landmarks on our maps. These landmarks are supported and linked over time by different events in order to come to certain conclusions about our identity. Morgan (2000, p. 7) uses an analogy of stars in the sky. Our eyes are drawn to familiar constellations, joining the dots in order to code

our experience. As therapists, we focus on finding different stars and forming new constellations or maps that can help show us a new direction that leads to a different more life-giving conclusion. In this way, we move from what is described as a thin description towards a thick description, a term developed in social anthropologist (Geertz 1973).

Recent developments that link neuroscience and narrative therapy show that our brains have more ability to change than we thought. Neural pathways are programmed into dominant fear-based maps that aid our ability to survive (Beaudoin and Zimmerman 2011). Finding exceptions to these pathways, alternate stories, supports our brains in creating new preferred maps that generate different experiences. These exceptions to the rule are not located in the thinking brain but rather built up through lived experience and relational practice in the stories we tell about ourselves.

This involves developing a thorough description of the territory as we map the trajectory of the problem story and how it has evolved and developed. After examining these maps, White suggests that exploring alternate maps helped him “to respond to people in ways that open for them to explore neglected aspects of the territories of their own lives. This provides people with avenues of possibility for addressing the predicaments and problems of their lives in ways that they wouldn’t have imagined” (2007, p. 5). People become curious about territories that they might have neglected or overlooked. A major influence in White’s earlier work was expanding on Gregory Bateson’s question “what restrains people from moving on with their lives?”. Bateson was interested in how organisms could code something new and called this “news of difference” in which an organism only changes over time when differences are recognized and coded (White 1986).

Externalizing Conversations

Narrative therapy is perhaps best known for the way it externalizes a problem and separates a person from its negative influence. White (2007,

p. 4) says “amongst other things, externalising conversations have made it possible for people to separate their sense of identity from problem-saturated or deficit-centred accounts of who they are, and this has provided a basis for them to join with others in the rich descriptions of alternative accounts of their lives, of their relationships, and of their identities.”

The iconic example of this was White’s work with a child who suffered from encopresis. The child called the problem “sneaky poo” (White 1984). Another example he gives (2007, pp. 11–22) is with a family who come to consult with him about their son who is diagnosed with ADHD. It is particularly interesting how he skillfully deconstructs the diagnosis by asking questions such as “what sort of ADHD does he suffer from?” and “how would you know what ADHD it looks like?”. There are many transcripts of conversations that demonstrate this way of externalizing (Morgan 2000; White 2000; Freedman and Combs 1996).

It is important to mention here that externalizing conversations are not about the individual autonomous self on a private journey. The skill involves a constant weaving of stories that are connected and in relationship with other people. It fosters a relational sense of identity (White 2000, p. 59). Freedman and Combs (1996, p.49) describes an externalizing conversation she had with herself. She had always considered herself a shy person. She changed her perception of shyness to the question “what are the effects of shyness in my life?”. This altered her experience of shyness and allowed her to begin a process of freeing herself from this limitation.

Developing a Preferred Story

A person came to consult with me concerning a very frightening situation he was about to go into; we described it as going back into the lion’s mouth. He came to rather a negative and thin conclusion about himself, describing himself as “passive-aggressive.” I asked him more about passive-aggression and what it had made him believe about himself. I also asked how it came about that he believed this to be true. He told me

of many times that he had given in to other people through fear. This had led him to being walked over. He described how ashamed he was of this behavior. I was interested in times where this has not been true. He gave an example of stopping in a dark tunnel in order to protect a homeless man who was being bullied. After the conversation, I asked him to write what was important to him in our conversation. This was partly to consolidate his experience of the session and also for me to get a better idea of the direction he wanted to move towards. This was the beginning of us generating new more empowering maps. It also offered us a way of recording our conversation. He was in control of his own words and notes. In the session, we had used a metaphor for this passive-aggressive behavior. It was like a person who comes upon a pride of lion. The person rolls onto his back into a subservient position, as a form of protection from being hurt. He writes:

This subservient position - don’t eat me, I am silent and harmless. I roll over in the company of dominant people - allow myself to be steamrollered, letting my boundaries be transgressed, not realising it until it’s too late. And yet, I am going back into ‘the lions mouth’. It is an act of courage - the boy going back down the tunnel to stand up for the homeless man. (An accurate metaphor). No fear of consequence in that moment. Simply ‘I must. It’s right’.

In this instance, we found what appeared to be an arbitrary incident of courage that contradicted the dominant story of passive-aggressive that had taken on a truth status, a sparkling moment that is waiting to take its rightful place in the story.

Questions are invited that interpret the problem as relating to a transition or rite of passage in a person’s life. Questions are oriented towards what they might be needing to separate themselves from. There would be a focus of enquiry about beliefs that are not helping them to move forward and finding out upon what assumptions these beliefs are based. The person is then asked questions that connect some past events when they might have done things that work and projecting this into the future as with the dark tunnel. In order to develop a richer description of this, we could ask what this knowledge might tell them about their problem-solving abilities. This opens up new

lines of enquiry that offer opportunities for particular markers on their maps, locating them all the time as experts on their own knowledge.

Markers on a Map

Alternate stories are built upon new evidence as it emerges. These become defining moments and provide experiences that give markers on a map where people can build up alternate stories. These stories become “rites of passage” (White and Epston 1990). A rite of passage allows a person or a community to reconstruct their journey. This separates the problem from the person and avoids classifications that diagnose problems as breakdowns or regression or dysfunction, metaphors that are associated with psychopathology.

Letters can be used as markers on a map. I once had a client who experienced particular isolation. He was challenging his sexual identity in a country where “gay” was considered a crime. We spent the end of each session writing about what we had talked about in the form of a letter from me to him, where I positioned myself as a witness on his journey from isolation to belonging. He contacted me some years later. He was distraught. He thought his box of letters had been stolen and these were some of his most precious belongings. Epston (1994) suggests that one letter can be as effective as three therapeutic sessions. Denborough (2002) makes use of song as a way of witnessing and building different identities. He used this on one occasion with a man in prison, for whom a written letter would have not been helpful as he had limited skills in writing and reading.

We frequently use a flip chart to mark our journey on. I particularly like working this way with pictures that we can build up. I find pictures and symbols capture size and space and position of a person in relation to a problem. A side benefit of this way of working reduces intensity as both therapist and client are exploring the picture on the board. It graphically positions the therapeutic alliance working together on a problem that is externalized on a board.

Outsider witnessing (White 2000, p. 165), what was earlier called reflecting teams

(Anderson 1987), is another way of forming a marker on a map. It involves the re-telling of preferred stories before an audience of carefully chosen outsider witnesses. This helps to shape different identities and thicken new stories. This is set in contrast to rituals and ceremonies that degrade or judge people in life (as can often be witnessed in today’s world on social media) or where someone is ganged up on in a work context or unfairly treated. This practice evolved from an earlier idea of what Peggy Papp (1980) called a “Greek Chorus” or “gossiping in the presence of.” The importance of an outsider witness group is that the group hold a conversation in front of, but not including, the client. The group focuses on their own experience of the conversation and what they might have learnt from the client and how this relates to themselves. It becomes a parallel knitting together of experiences that are not coming from a top-down or expert position.

Celebrations can be used or certificates for young people. Re-membling groups can be generated where a person selects people who they would like to play on their team. These become support groups for alternate stories that are supported in community action.

A Background History

Narrative therapy straddles a time in history that has been moving from a modernist worldview towards a post-modern perspective in which identity is more fluid and constantly changing, depending on the context and time in history we find ourselves in and this shapes our perceptions of life (Burr 2003; Hart 1997).

The first wave of the movement began in the 1960s. Groups in North America, including social anthropologists, social scientists, human biologists, social workers, and psychiatrists, began to move away from models of psychopathology that had influenced psychology over the previous 100 years and explore some of the ideas emerging in the social sciences.

What they all had in common was an interest in the human species and how it evolves and changes within its larger environment. This was very

different ground to be exploring in the dominant climate of psychology. It turned away from intrapsychic psychology that had been using metaphors that focused on the health and medical diagnosis of an individual person, towards how people function in groups, and what helps them change and evolve.

It shifted the thinking away from understanding a person as broken or in need of fixing, to an evolutionary idea of adapting and changing.

The movement began looking at families in a more holistic way, where the individual was a part of a much larger system that functioned within certain rules and conventions. This gave rise to systemic family therapy. In this first wave of systemic thinking, problems were understood as a symptom of family functioning. Postwar metaphors were used, borrowed from cybernetics, in which families were normalized as closed systems of homeostasis (as in a central heating system). The metaphors shifted and changed with the times to communication theories and dysfunction. These were all machine-like metaphors that were and still are used. The movement was influenced by social constructivism, particularly the work of Maturana and Varela who explored the biology of perception and cognition of the nervous system as it feels its way towards safety (Freedman and Combs 1996, p. 26).

The second wave in family therapy took many of its metaphors from literary criticism and the arts embedded in postmodernist thinking (Lowe 1991). These movements challenged some of the earlier assumptions around families as closed systems or feedback loops. It continued to evolve towards the next wave of family therapy where power, gender, and inequality were taken seriously.

Birth of Narrative Therapy as a Social Construction of Reality

These earlier movements gave rise to narrative therapy, which moved away from understanding families as systems. The boundaries between the self and other, expert, and patient began to

dissolve and narrative therapy as we know it today was birthed by Michael White in Australia and David Epston in New Zealand. They brought out a book called *Narrative Means to Therapeutic Ends* (White and Epston 1990). They integrated into a therapeutic model the ways in which power and knowledge work and deconstructed language in a way that was empowering to those who came to consult with him. Their careful use of language was a constant deconstruction of some of the taken-for-granted assumptions, selecting words that did not pathologize. They articulated in the therapeutic world much of the philosophy at a time when certainty was in the dock and truth was being cross-examined. It was a heady era in philosophy where words in the post-structuralist and social constructionist movements were not understood as having any hidden meaning of truth but were contextual.

They traced how meanings and metaphors were used over history in order to make sense of the world we live in, particularly how Foucault systematically unpacked the assumed truths of each age and showed how certain experiences have become enshrined and given the status of truth. Building on this, narrative therapy began to challenge the idea of a singular description of a person in favor of multiple stories that evolve over time.

This introduced an epistemological shift in the way we see and understand the world, moving from modernist notions where reality and facts are knowable, towards understanding life as a social construction of reality. Parry and Doan (1994, p. 1) say “Once upon a time, everything was understood through stories. Stories were always called upon to make things understandable. . . . The answers they gave did not have to be literally true; they only had to satisfy people’s curiosity by providing an answer, less for the mind than for the soul.” It is the meaningfulness of the answers given rather than their factual truthfulness that gives beliefs credibility. In a therapeutic sense, this can mean that people get trapped and labelled within dominant beliefs until new meanings emerge from parts of a story that were not considered important.

It concludes all the things that make up the psychological fabric of “reality” arise through interaction over time. “People together construct their realities as they live them and make meaning from them” (Freedman and Combs 1996, p. 23). Some years ago, when visiting Botswana, I was reading a book about the bushmen/San of the Kalahari Desert. They consistently raised four children. The explanation was simple. Four was a sustainable number for the group. They had a ritual that any subsequent baby was taken into the desert by the mother and the mother returned empty-handed. This creates an evolving set of meanings created in social interaction that help a group to survive. It could of course be constructed that she was a murderer.

Deconstructing the Text

Derrida’s work on deconstruction influenced and helped to craft how language is used in the movement. Words assume socially sanctioned meanings that form our thinking and constitute our world (Anderson and Goolishian 1988; Foucault 1970; Burr 2003). Take the word God for example. There is a dominant construction, which is not said but implied, that of a male patriarch who lives in a separate domain. This word has changed and evolved to favor words like “the divine” which embraces a more Eastern texture of global wisdom, creating more space and collapsing the boundary between God and me. Derrida pointed the way to understanding that what is not written is as important as what is written; what is said always stands in relationship to what is not said. Narrative therapy explored this by asking questions that find out what lies between the lines of dominant texts, what is not said but assumed. This is what Bruner, Vygotsky, and Derrida had called “the absent but implicit.”

Deconstruction is used in narrative therapy to formulate questions that challenge the taken-for-granted assumptions in order to find where there is not a problem. White refers to this a “re-authoring” of stories. Dominant pathologizing stories are overtaken by other preferred life-giving

stories that were not previously considered of importance.

Deconstructive Questions

I have given some examples of deconstruction in action. Questions such as “how did you come to believe this about yourself?” or “what was shyness trying to do to you?” or “Was there a time when this negative belief about yourself was not true and you stood up to passive-aggression?”. Other deconstructive questions that begin to build up alternate descriptions of the map might be “Who else knows this about you?”. All of these questions challenge the pathology of identity and assume that a person is so much more than their problems.

Deconstructive questions unpack some of the assumptions around which, for example, a pathology survives. Morgan (2000, p. 45) writes, “Anorexia and bulimia nevosa can only survive in cultures that value thinness, where success and competence are judged in terms of body shape and size and in cultures which promote self-surveillance and individualism.”

Conclusion

Narrative therapy takes a critical stance toward taken-for-granted knowledge and how we position ourselves within a therapeutic relationship. It also understands how violent language can be in the way it is constructed. In this way, narrative therapy pays great attention to language and its multiple meanings. It challenges some of our taken-for-granted truths of our age, reflected both in the way we live in a Western society and the therapies that we practice (Hess 2006). Narrative therapy opens space for new possibilities of experiencing life to happen. It challenges problems and the restrictive grip they have on us, as well as opening up new possibilities of stories waiting to be told. It has contributed to the conversation by inserting post-structural theories and turning them into conversations.

This moves from words such as “expert,” “diagnosis,” and a “patient” towards a deep collaboration of shared knowledge and power within a community of “knowing.” It draws attention to both culture and history and explores people as socially constructed beings who make sense of their world at a certain age and time in history. In this way, it moves away from intrapsychic ideas of the individual autonomous “self” towards identity being a multistoried affair of life-giving preferred identities.

Narratives

Emily LeRoux-Rutledge

University of the West of England, Bristol, UK

Abstract

While many definitions of narrative exist, at its most basic, a narrative is a temporal sequence of events with a plot connecting those events. When we express our identity – who we are – we often do so in narrative form, telling a life story that helps us to understand, and indeed to construct who we are. This involves not only making sense of our past, but also shaping how we want to be seen in the present, and imagining who we could become in the future. Indeed, whenever we think back, selecting events from our past to construct our life stories, we are simultaneously communicating our goals and

aspirations for our future possible selves. Such goals and aspirations, however, are always constructed in particular social contexts, and these social contexts provide narrative templates, or *public narratives* – such as “rags to riches” – which afford models for our stories. Public narratives can be difficult to pin down (they are usually not written down anywhere), but we can think about them as the aggregate of many stories. Importantly, they are normative, and widely known, communicating what constitutes a good life for a person like us, in our culture. Against their backdrop, we negotiate our personal stories. Public narratives are not fixed, however, and they are multiple, even in a given culture. Consequently, there is a debate among narrative scholars about whether we select and *use* public narratives to construct ourselves, or whether *they construct us*. Ultimately, most scholars recognize that the interplay is dynamic; for, while it is true that we are in some sense constrained by the public narratives available to us in constructing our life stories, it is equally true that, if enough people reconstitute their life stories, these can reconfigure public narratives themselves – opening up new possible ways of living and being. Herein lies the possibility for social change.

Keywords

Narrative · Identity · Self · Aspiration

Introduction

There is no agreed definition of narrative – a point on which most narrative scholars agree (Squire et al. 2013). Common to most definitions are two structural features of narrative: *temporal sequence* and *plot*. Definitions of narrative tend to emphasize time, or temporal sequence (Andrews et al. 2013; McAdams 2001; Rappaport 2000; Ricoeur 1984; Sarbin 1986). Laszlo, for example, defines narrative as:

Accounts of events, which involve some temporal and/or causal coherence. ... [and which require] some goal-directed action of living or personified actors taking place in time. (Laszlo 2014, p. 3)

Temporal sequence, however, is not sufficient to define narrative; there must be *implied causation* linking one event to the next (Murray 2003; Squire et al. 2013). Implied causation is what makes narratives different from chronology. A list of occurrences, in which events follow each other but have no apparent relation to one another, is generally *not* characterized as narrative (Czarniawska-Joerges 2004). In narrative, events are inferred to have occurred *because* of the events preceding them. Causal inference is what starts to turn chronology into a story. This is what gives narrative its *plot*.

Plot is the second structural feature central to most definitions of narrative (Bruner 1986; McAdams 2001; Murray 2003; Sarbin 1986; Somers 1994). The plot connects narrative events together and gives them significance. It is the plot that gives a narrative its meaning. Although temporal sequence and plot are the *defining* structural features of narrative, narrative scholars have also drawn attention to other structural features – including *beginnings, middles and endings*, and the *dual landscape* (Booker 2004; Boonzaier and Schalkwyk 2011; Riessman 2008). Some of the scholars who adhere to this view of narrative go so far as to claim there is one *universal* story structure, which can describe all stories. Laszlo characterizes the universal structure as follows:

A full blown narrative involves an initial steady state which implies the legitimate order of things including the characters' normal wishes and beliefs, a trouble which disturbs this state, efforts for re-establishing the normal state, a new, often transformed state and an evaluation in conclusion, which draws the moral of the story. (Laszlo 2014, p. 3)

However, there have been various challenges to the claim that stories have a universal story structure, or a beginning, middle, and end – notably, by scholars who study political narratives and personal life narratives. Scholars such as Andrews (2007), who study political narratives, argue that political narratives do not have endings, because that would imply no future. It would imply, in a sense, that all of society's problems had been solved; therefore, political narrative must always be unfolding. Similarly, human lives are also

constantly unfolding. As Crossley (2000) explains, we are always in the middle of our stories, while Andrews maintains that the only beginnings, middles, and endings to be found in personal life narratives are those which are artificially attributed (2007). This makes the notion of beginnings, middles, and endings somewhat problematic.

Another notable feature of narrative structure, which some scholars consider central, is its *dual landscape* (Bruner 1986; Laszlo 2014). Narrative often takes place on a landscape of *action* and a landscape of *consciousness*. The landscape of action is where we see the events of the story play out. The landscape of consciousness is where we come to know the inner worlds of the protagonists, including what they know, think, and feel. This is important because narratives are often not only about what happens, but also about what human beings *intend* (Bruner 1986; Laszlo 2014; McAdams 2001). Recognizing that stories have a dual landscape opens up narrative to the study of meaning. According to Laszlo:

When [Bruner] amended the landscape of action (what characters do in a story) with the landscape of consciousness (what we know about their beliefs, intentions, wishes and emotions), he opened up the opportunity for studying the meaning of actions. (Laszlo 2014, p. 4)

The Narrative Conceptualization of Identity

Meaning is what narrative is really about, and when we tell stories about *ourselves*, we are typically using narratives to construct our identities. Identity is often understood as the answer to the question “Who am I?” Definitions of identity are extremely diverse in the social sciences (Ramaraajan 2014); however, a range of scholars advocate approaching identity as narrative (Bruner 2004; Laszlo 2014; McAdams 2001; Somers 1994). Such an approach allows us to recognize that the primary way in which we make sense of ourselves, the social world, and our place within the social world is through narrative (Bruner 1990). People tell themselves, and

others, *stories about themselves* in their social context, which help them to understand – and indeed, to construct – who they are, and to frame their possibilities for action (Bruner 2003).

Aspirations, Goals, and Possible Selves

Telling life stories involves engaging with the past – creating meaning out of, and making sense of, the things that have happened to us in our lives. It also involves engaging with the present – building a picture of who we are, and how we want to be seen. Finally, and crucially, it involves engaging with the future – aspiring, planning, and imagining who we could become (Boonzaier and Schalkwyk 2011; Bruner 2003; Mankowski and Rappaport 1995; Polkinghorne 1988).

Ideas about the future may be *explicitly* narrated in the course of a life story. In particular, a person may tell stories about who they could, and would like to become. According to Markus and Nurius, goals and aspirations always take the form of imagined *possible selves*; they are never abstract (1986). For example, although we may say that we aspire to education; really we aspire to *be* an educated person. The way we aspire is by constructing scenarios about who we *might* be, who we *want* to be, and who we do *not* want to be. This fits with the thinking of narrative scholars who argue that hopes, dreams, and aspirations are narratives (Crossley 2000; Laszlo 2014; Sarbin 1986). Within a personal life story, one sometimes finds such aspirational narratives expressly articulated. For example, a South Sudanese woman narrates:

I want to bring my little brothers, my younger brothers, up, to make them go to school. If I have [the] power of supporting them, then, to at least make them learn, not to be like me. ‘Cause as you understand I’ve already broke out of school and I don’t know whether I will go back or not. So, I’m willing to take them to school and make them learn, get what they want in future. (LeRoux-Rutledge 2020)

There is a clear story here, in which the narrator sees herself bringing up her younger brothers, impressing upon them the importance of

education, supporting them through school, and witnessing them realize their dreams. Hypothetical stories like this are not the only way in which goals and aspirations can be gleaned from life narrative, however. Goals and aspirations – clues about who a person wants to be in the future – are also contained within stories about the past and present. Bruner gives this example:

The Self as narrator... is always, as it were, pointing to the future. When somebody says, as if summing up a childhood, 'I was a pretty rebellious kid,' it can usually be taken as a prophecy as much as a summary. (Bruner 1990, p. 121)

Bruner maintains that whenever we think back, and select events from our past, to construct our life stories, we are simultaneously shaping ourselves for our imagined future (2003). Laszlo similarly maintains that one's life story is really an identity plan, communicating ones wishes, goals, and aspirations (2014). Inferring goals and aspirations from a person's life narrative is not, therefore, an analytical exercise limited to those portions of the narrative that *explicitly* deal with the future. Clues about aspirations – who we feel we could become – can be found in stories of the past and present. Interestingly, this means that, despite our ability to continually reconstruct our identities throughout our lives, and from one context to the next, we can also become constrained by our life stories, becoming trapped within our stories and so setting up limits to our possibilities for the future, as we *become* the stories that we adhere to in our daily lives (Bruner 2004). It is thus an interesting and paradoxical feature of narrative identity that we both control it, and it controls us.

Personal Narratives in the Context of Public Narratives

Then there is the importance of the social context. Somers (1994) has highlighted two important elements to studying narrative identity, the personal narrative, and its social context. She is not alone in this; most narrative scholars recognize the importance of social context in the study of personal stories (Bruner 2004; Hammack 2008; Laszlo

2014; McAdams 2001; Phoenix 2013). Central to the social context are *public narratives*, “those narratives attached to cultural and institutional formations larger than the single individual” (Somers 1994, p. 619). Examples of public narratives include: “American social mobility,” “the freeborn Englishman,” and “the working-class hero” (Somers 1994, p. 619). Different scholars call public narratives by different names. Some call them *canonical narratives* (Bruner 1986), some call them *cultural narratives* (Crossley 2000; Squire et al. 2013), some call them *meta-narratives* (Andrews 2007; Plummer 2007), and some use terms like *public narrative*, *social narrative*, and *cultural narrative* interchangeably (Somers 1994). The point of commonality, however, across all terms, is that they refer to stories which are not unique to individuals.

Public Narratives, Aspirations, and Possible Roles

Despite using different terminology, these scholars of narrative identity express a common idea: that public narratives form the backdrop for life stories. Moreover, because, as we have already seen, life stories are intimately linked to personal aspirations, public narratives form the backdrop for personal aspirations as well. This is unsurprising, because such narratives often provide models of the intentions, goals, and values typical to people in a given culture. The narratives thus provide templates of how to live one's life (Mankowski and Rappaport 1995). Just as individuals have repertoires of *possible selves*, including selves they *do*, and *do not*, want to become (Markus and Nurius 1986), so too do the larger stories of a culture contain a repertoire of *possible roles*, with indications about which are desirable and which are undesirable:

Stories define the range of canonical characters, the settings in which they operate, the actions that are permissible and comprehensible. And thereby they provide, so to speak, a map of possible roles and of possible worlds in which action, thought and self-definition are permissible (or desirable). (Bruner 1986, p. 66)

Public Narratives As the Aggregate of Many Stories

Since public narratives outline *possible roles*, they are often referred to by the *names* of those roles. As we have seen, Somers' examples of public narratives include: "the freeborn Englishman" and "the working-class hero" (1994, p. 619), while Rappaport's examples of dominant cultural narrative include "welfare mother, college student, [and] housing project resident" (2000, p. 4). Rappaport explains that such roles often become shorthand for the stories that lie behind them.

Expressing public narratives, however, can be challenging. Sometimes scholars express them *as stories*. For example, Hammack writes the narrative of Israel as a story, which begins: "In 1948, a nation emerged from the ashes of the Holocaust. The sandy shores, fertile soil, and mountainous beauty of their original homeland once again welcomed them. . ." (Hammack 2008, p. 222). Most of the time, however, scholars describe elements of the public narratives, such as *who* and *what* the stories are about, and what *point* they make. For example, Phoenix describes, "*it is worth standing up for your convictions*," as a narrative, and, "*racism is illegitimate and to be opposed*," as a narrative, even though these are clearly points that narratives could make (Phoenix 2013, p. 1971).

One of the reasons why it is difficult to express public narratives as narratives may be the absence of authoritative texts. Unless scholars have an authoritative text, such as the Bible (see Tribble 1984) or "The Big Book," which is the primary text of Alcoholic Anonymous (see Humphreys 2000), or a specific narrative in the media, there is usually no formal version of a public narrative that can be referenced.

In a sense, a public narrative is actually an *aggregate* of all the stories that get told about a certain kind person or event, or that make a certain point. These stories may have a common structure, but public narratives are generally *more* than basic plots (Booker, 2004), archetypes (Frye, 1957), or genres (Bruner, 1986). There is content to them that makes them at least *somewhat* historically and contextually specific. A good example is Salzer's study of what he calls the "societal-

level narratives" of housing project residents (1998). By asking 100 people who did not live in housing projects to write a short story about a housing project resident named Ann, and by analyzing the stories thematically, Salzer was able to construct a standard example of the public narrative about housing project residents:

Ann . . . always dreamed about getting out of public housing. She has lived in public housing all her life. . . [The place where she lives] is poorly maintained and crime-ridden. While in high school, Ann met a nice guy and thought she was in love. She got pregnant by him and dropped out of high school. This guy left her after the child was born. Ann got pregnant again and had a second child. Ann wanted to go to college, but can't because she lacks the funds to pay for it. Ann has a hard time finding work because of her lack of education and day care resources for her children. She is able to find work at a fast food restaurant. There is a lot of death in Ann's life. Ann is depressed. She will never make it out... (Salzer 1998).

As Salzer explains, this narrative was not related by a single individual; it was his attempt to aggregate the accounts of many individuals, and he presented it with the caveat that no single story could accurately capture all possible combinations. Thus, when we talk about *public narratives*, we must recognize that, except in rare cases, no single telling of them will fully encapsulate all of the variants that can be told. This does not mean that public narratives are not narratives, but it does mean that they are sometimes described non-narratively, with reference to their characters, themes, or morals.

Public Narratives As Normative

A key thing to realize about public narratives is that they are often normative. They explain how one ought to live one's life in a given culture, illuminating what an ordinary life looks like (Bruner 1990; Phoenix 2013). They elucidate for us good and bad ways of being. Crossley, summarizing Taylor (1989) explains:

One of our basic aspirations is the need to feel connected with what we see as 'good' or of crucial importance to us and our community. We have certain fundamental values which lead us to basic

questions such as ‘what kind of life is worth living?’... A vision of ‘the good’ becomes available for people in any given culture... Stories have a tremendous force in this process insofar as they have the capacity to confer meaning and substance on people’s lives, to subtly influence their progression and orientation towards a particular ‘good’. (Crossley 2000, p. 16)

That is not to say that public narratives in a given culture all present *the same* vision of good. According to Bruner, cultures are made up of connecting stories, which do not necessarily represent consensus (1990). Rappaport, for example, highlights the lack of consensus in two public narratives of people with mental ill health in the United States. In one narrative, typically advocated by mental health professionals, the good life is taken to be one in which a person with mental illness is able to live an independent life (2000). An alternative narrative, advocated by community-based mental health organizations, cherishes communal living, maintaining that the good life for a person with mental illness is one in which he or she is part of a caring community. This shows how public narratives, even those about the same kinds of people, can be in tension with one another.

Such tensions are important, because stories in tension can offer competing visions of what to *do*. Should a mentally ill person live alone, or in a group setting? Narrative ultimately matters because it impels us to *act*. As Somers puts it:

Research is showing us that stories guide action... that people are guided to act in certain ways, and not others, on the basis of the projections, expectations, and memories derived from a multiplicity but ultimately limited repertoire of available social, public, and cultural narratives. (Somers 1994, p. 614)

This is, ultimately, why public narratives matter. Public narratives can affect which individual actions are possible (Hammack 2008).

The Dynamic Interplay of Personal and Public Narratives

Public narratives are not fixed, however, and Squire and colleagues have highlighted that,

among narrative scholars, there is a debate about whether we *use* public narratives to construct ourselves, or whether *they construct us* (Squire et al. 2013). Sometimes narrative scholars choose to stress how we are *constrained* by public narratives (Phoenix 2013; Somers 1994). At other times scholars stress people’s *agency*, and the ways in which they use narratives as *resources* in the process of identity construction (Bruner 2004; Crossley 2000; Hammack 2008). Mankowski and Rappaport, for example, discuss how people appropriate public narratives into their own stories to construct, maintain, or change identities (1995).

Narrative scholars usually recognize that there is a dynamic interplay between personal and public narratives. In particular, that we both *use and* are shaped by public narratives (Bruner, 2003; Crossley, 2000; Markus & Nurius, 1986; McAdams, 2001; Rappaport, 2000; Somers, 1994). McAdams talks about life stories being co-authored by the individual and his or her cultural context (2001). Markus and Nurius make the same point about identity:

An individual is free to create any variety of possible selves, yet the pool of possible selves derives from the... individual’s particular sociocultural and historical context and from the models, images, and symbols provided by the media and by the individual’s immediate social experiences. (Markus and Nurius 1986, p. 954)

Personal identity narratives, then, are negotiated within a wider symbolic field, which provides symbolic *resources* for the construction of personal narratives. Public narrative resources form part of the “symbolic context” of societies: “the meanings, ideologies and worldviews circulating in particular social settings, through which people understand themselves, others and the activities they engage in... [and which frame] how different groups are valued and respected” (Campbell and Cornish 2010, p. 848).

It is important to recognize the fluid and constantly negotiated nature of these symbolic resources, because when enough people reconstitute their personal identities, these can reconfigure public narratives (Andrews 2007; Hammack 2008; Mankowski and Rappaport 1995). As Hammack explains, “personal narratives can disrupt dominant

discourses in a society, thereby destabilizing master narratives of identity” (Hammack 2008, p. 237). Individual narratives, therefore, can expand what is possible for everyone in a society. Herein lies the possibility for social change.

Norms

Martina Cabra

Institute of Psychology and Education, University of Neuchâtel, Neuchâtel, Switzerland

Abstract

Norms can be defined as sets of relations that define forms of communicating, feeling, acting, and thinking. They define what is allowed and what is not allowed to be said, felt, done, or thought. They are situational and relationally negotiated. Usually described in terms of their functions (descriptive, constitutive, prescriptive), the term commonly designates prescriptive guides. Norms can be more or less explicit, more or less prescriptive, and be more or less opposed and resisted. Authors mostly agree on the fundamental character of norms for human life. Operating at a collective and a psychological level, they guide and constrain human lives. And although sometimes viewed as limiting possibilities rather than creating them, they can be seen as producing a certain set of possibilities and transformed through our engagement with them in our relations to others.

Keywords

Social norms · Psychological norms · Development

Introduction

Human lives are filled with social and personal expectations, rules, and prescriptions. Our deepest wishes, desires and anxieties are marked by social, cultural, and relational norms. We are scared to wish for someone's company, do not dare to dream of a certain trip or get excited when imagining a radical change in our lives that we will never do. What we do is perceived, judged, and evaluated by others. A 4-year-old flying a kite, a woman speaking in public at the municipal council or a group of teenagers

drinking in church can be sanctioned, frowned upon, or applauded. Judgments and evaluations based on socially shared norms leave traces in people's lives; they mark us in more or less lasting ways. Yet, the way in which norms mark us is not determining: a young kid can drop out of medical school and form a punk band and an unhappy worker can stay at his job while secretly plan a revenge from his boss. From absolute rejection to strict compliance, people are not just evaluated or perceived, and they also find all sorts of ways to deal with these norms. Norms organize our social lives and define us, but we also have a part in defining them. They are shared and socially defined, but also psychologically reconstructed and internalized. People breach this gap in different ways and change what is expected, what is normal, or what is mandatory, moving the boundaries of the possible making thinkable the unthinkable.

In the literature on norms, there are many terms that resonate with the notion of norms: laws, rules, orders, customs, and prescriptions can be considered as referring to a similar phenomenon. Different disciplines have in their own way defined the terms more or less empirically, and more or less conceptually. To address the phenomenon which is of interest here, I define in the broadest possible terms as "that which is allowed and not allowed," in what follows, I adopt a psychological sociocultural perspective and organize the different notions around this phenomenon. I first present the anthropological definition of laws, rules, and norms and build on it to provide a disambiguation of the terms. I then review the classifications of norms that have been proposed. Thirdly, I look at the approaches interested in norm construction. I finally argue that what the studies on norms have in common is the recognition of a twofold existence, operating at a social and at a psychological level. Sociocultural psychology as a discipline is precisely concerned with the mutual constitution of the social and the psychological, and I thus propose, within this approach, to complement the definition, classification, and construction of norms in understanding their relation to the possible.

Laws, Rules, and Norms

Anthropologists' encounters with foreign societies, where people acted very differently from what was known and expected, inaugurated a body of research that studied the characteristics of what they called "primitive" people and societies. Particularly, these differences raised the question of whether there was chaos or some type of order in how they functioned. Studies conducted by scholars such as Malinowski, Steinmetz, Durkheim, among many others, came to the conclusion that there were indeed forces creating "order, uniformity and cohesion in a savage tribe" (Malinowski 1926, p. 19) and they defined them in terms of laws, rules, and norms.

Malinowski (1926), a central figure to understand norms in anthropology, explained that the laws and traditions that regulate all human life emerge from the "biological, mental and social needs of human nature" (Malinowski 1926, p. 20). With this claim, he enunciated the fundamental character of laws in human lives – in any society. Laws are here universal and founding of the group's existence. Another prominent figure in the study of norms in anthropology is Claude Levi-Strauss, who equally defined laws through their universality and founding character. He stated that "the absence of rules is a clear criteria to establish the distinction between natural and cultural processes" (Levi-Strauss 1949, p. 12). In his understanding, laws, as they are universal, pertain to natural processes, while rules and norms to cultural ones. Based on this distinction and in a language play, he termed the prohibition of incest, law of incest, as he considers it the only human norm that has the characteristics of the natural processes, sharing its universality and founding the distinction between the natural and the cultural.

Malinowski (1926) further distinguished types of rules, based on the motives that back them up. There are rules that are followed because their practical utility has been confirmed by reason and experience. Others are followed because if the person were to move away from them they would feel shame and embarrassment. There are still others, such as those regulating games that are

followed because if they are not followed "the game" would be ruined. What he stated is that, in this type of rules, there are no "mental forces" or "personal interests" that could contradict them and make following them a heavy load. It is for him as easy to follow as to not follow these kinds of rules. Differently, there are other rules that are sacred and important. These are backed up by strong convictions and the possibility of supernatural sanctions that would be imparted if not followed. Different still are customs, which are norms that are implicit in everyday life activities and actions. This classification allows him to state that, aside from the law that regulates the functioning of a society, there are other types of norms and traditional mandates that are backed up by motives and forces that are mainly psychological. He thus frames rules and laws as defined categories of the body of customs and social rules (Malinowski 1926).

Both Malinowski (1926) and Levi-Strauss (1949) were interested in understanding how order is produced in societies. Similarly, as we will see, psychoanalysts such as Sigmund Freud and Jacques Lacan attempted a similar effort in understanding what organizes psychism. Their work on laws can be considered the corollary attempt to understand such universality in psychism. In both cases, scholars defined a constitutive function of norms in human lives (in societies or psychism) by proposing their universal character (although varied content) for defining how norms appear in each situation.

To address the phenomenon which is of interest here, that which is allowed and not allowed, in what follows, I maintain the term law for universal norms; rules for explicit norms; customs for implicit norms; and norms in themselves as relations defining forms of communicating, acting, and thinking, situational and relationally negotiated.

Classification

Across these terms, there have been attempts to classify norms depending on their function and their level of analysis (see Table 1).

Norms, Table 1 Perspectives on norms

		Function		
		Prescriptive, regulatory, injunctive	Descriptive, technical	Constitutive, determining Institutional
Level of analysis	Social Collective Group	i.e., “people must cross the street when the light is green”	i.e., “if you want to turn on the TV, press the left button”	i.e., prohibition of incest
		von Wright, Searle, Winther-Lindqvist, Moscovici, Jodelet, Malinowski, Cialdini et al.	von Wright, Cialdini et al.	von Wright, Searle, Levi-Strauss, Butler, Malinowski
	Individual Psychological Perceived Personal	i.e., “girls cannot play cowboys”		i.e., threat of castration
		Piaget, Tomassello, Vygotsky, Harris, Winther-Lindqvist		Searle, Levi-Strauss, Freud, Lacan, Butler

When it comes to defining the function of norms, there is one main distinction that authors have made: there are prescriptive, directive or regulatory norms (Nino 2013; Searle 1997; von Wright 1963), descriptive or technical norms, and constitutive or defining norms (Searle 1997; von Wright 1963). The first and second ones organize or describe an already existing set of things, while the third defines what is considered reality, they are norms that found the very objects to which they refer. Although referring broadly to the same type of statements, the authors chose different names for them depending on the aspect of the norm they want to foreground. For example, some choose to call a norm injunctive rather than prescriptive, allowing to include also the proscriptive effect of prescriptions (Cialdini et al. 1991). To prescribe is to define which way something ought or should be done, but with no explicit reference to what is not possible or not allowed. The word injunctive carries both the prescriptive and proscriptive aspects of guidance. If we consider the case of a child being told “you must learn to use the toilet now,” the action of using the toilet is prescribed, but that of not using diapers anymore is proscribed. Calling the norm injunctive allows pointing to impossibilities as well as possibilities but, as mentioned, the terms are chosen by the authors depending on the aspects of norms they wish to foreground.

Constitutive norms create the act they enunciate, giving it a new status or function (“X

functions as A in B”). As when a white flag was decided to be symbol for truce, they transform the stick and the piece of cloth into a new object, indicating actions to those involved (stop fighting, drop your weapons). Technical norms, quite differently, are more descriptive. They do not seek to guide conduct in a certain direction but state a hypothetical situation, such as “if you wish to turn on the TV, you must press the left button.” These describe an already defined state of things and enunciate a possible course of action. Last, prescriptive norms are those, in which the speaker tries to direct the others’ behavior, inducing him to adopt a certain course of action – such as “children must brush their teeth before bed.” It may be interesting to consider that norms, which are considered constitutive at a certain point in time, may become prescriptive at another and, thus, possibly changed or contested. A group or individual might consider a norm in one or another category, as has been the case of gender differences once thought of as “natural,” increasingly revealed as socially constructed and thus possible of change.

In terms of their level of analysis, norms can be individual or social, although there is no agreement in the terminology employed – personal (Cialdini et al. 1991), perceived (Chung and Rimal 2016), individual (McKirnan 1980), or subjective (Kelsen 2003); as per the social, authors refer to collective (Chung and Rimal 2016), societal (McKirnan 1980; Sherif 1936), or de-psychologized (Kelsen 2003) norms.

Across these propositions, norms have then been distinguished in terms of their function (constitutive or regulatory) and defined as statements (explicit or not) guiding or prescribing conduct in a certain direction. The authors' claims can be interpreted as proposing that, as some of the norms are constitutive, they are creating a certain field of possibilities; while the others merely provide order to such constituted states.

Norm Construction

I will now consider the approaches not interested in defining or classifying norms, but in their construction and development. Social, cultural, and developmental psychology, as well as psychoanalysis, provide different contributions to understanding such processes.

Norms as Frames of Reference

Sherif's (1936) pioneer work on the psychology of social norms was one of the first attempts to study norms at a psychological level. He showed, in an experimental setting, that there are frames of reference from which we interpret a task or understand a situation that are socially constructed. These frames are for him defined by social norms that can be contextually available or individually created. In the presence of an ambiguous stimulus, such as a moving dot of white light in a dark room, the person will either use situational queues to make sense of why it moves, or create relations with prior experiences to interpret it. What Sherif's experiments showed is that "if no norm exists in an uncertain and ambiguous situation, then individuals generate one such that their judgments do have a reference point" (Abrams and Levine 2012, p. 55). These norms can be "values, customs, stereotypes and conventions" (Sherif 1936, p. 6), among others, and can change for example, if a person is alone or within a group. For him what is commonly understood in psychology, as "variation in culture" is merely a variation of a frame of reference, made of social norms, relationally and situationally constructed.

Other social psychologists who studied norms, such as Asch (1951) and Milgram (1963), were interested in when and where certain norms or rules were followed, ignored, or transgressed; however, Sherif asked the more fundamental question of how norms were constructed. It is the presence of others, the presence or absence of elements in the situation that could be linked to the perceived phenomenon that participate to the creation of norms and to the frames of reference that are used to interpret the situation.

Normalisation in Groups

Serge Moscovici (1974) termed "normalization" the process through which norms are constructed at a group level. The definition of this process echoes Sherif's (1936) idea that in small groups, norms and frames of references become established through convergence of the members' view toward consensus. Yet, normalization here does not designate the person's conformity to norm as Sherif considered, but conformity to pressure toward group uniformity (Cohen 1978; Moscovici 1974). Moscovici and Faucheux (1972) label normalization and conformity, two processes that can be alternative styles of dealing with norms. As Cohen (1978) puts it:

Normalization contributes to the operation of group norms because pressures toward uniformity lead to the crystallization of norms in the first place (...) norm formation is itself a type of conformity, then the overall conformity process has two parts: (1) the development of norms through pressures toward uniformity, and (2) the operation of established norms. (Cohen 1978, p. 443)

Group norms can then operate both as frames of reference structuring people's interpretations of situations and as rules or ideals governing what members ought to and are expected to do and think.

Psychic Roots of Social Norms

Other studies on the construction of rules and prohibitions in societies refer to the fact that groups build shared prohibited actions, topics, or themes through practices and collective discourses, and

that some of these remain unspoken or undone because of their psychological roots.

For instance, Denise Jodelet (1989) studied how a community dealt with “madness,” notably by creating a social separation between the “madman” and the “sane.” She identified that to accomplish this separation there were institutionalizing and signifying practices. The first ones defined prohibitions around the mad persons – for instance, it was not possible to mix the laundry of the “mad” and the “sane.” The second support prohibitions through different representations – the mix is not allowed because there was a risk of pollution as the “mad” person is “dirty.” Between these two types of practices, Jodelet (1989) argued there was “something private.” This “something private” was, for her, related to villagers’ experience of the threat of the loss of individuality. There was a real fact – the encountering of other people, and differences with them. But villagers spoke of contagion, of the impurity of the other’s body, of a kind of pollution through contact that evoked, she claimed, the sexual, bodily, phantasmatic aspect of fusion of bodies, or the loss of individuality at a more profound level. In other words, she made the hypothesis that there is a defensive psychic root of this institutional instauration of a social difference.

Psychoanalysis, while exploring the unconscious (Roudinesco 2007) also defined the psychic roots of norms. Freud (1923) proposed there is a psychic instance, named the Superego, which is the moral instance of the psyche. The Superego is considered the place from where feelings of guilt emerge; it establishes how the subject should behave, think, and feel (Freud 1923). From a genetic perspective, this instance is the result of the abandonment of the real-life investment of the parental figures. This abandonment is actually an internalization of these figures, and the emergence, psychologically, of an instance that substitutes their function. Freud claims that the very intense feelings toward the parental figures young children display are abandoned because of the dangers they could bring – it is expected that the child diversifies his objects of affection and

substitutes the sole love for parents by other members of the group. Such an abandonment is, from this perspective, founding for the psychological organization itself.

If we take the terminology defined before, the impossibility to have sexual relations or erotic feelings toward the parental figures can be considered a law, a constitutive or institutional rule, as it found the way in which psychism is organized.

In the Lacanian return to Freud, the ways in which such a conflict – between the drive directed at the parental figures, and the prohibition of such relation – is resolved by defining a universal relation of the subject to the law. In each situation, this resolution defines a specific way of dealing with rules and constructing norms. The possible solutions are repression, renegation, and forclusion (Lacan 1958). For instance, the repression of the so-called law of the father, that is, the impossibility to marry one’s mother, leads to all sorts of neurotic solutions. In obsessive neuroses, people transform desires and wishes into imperative demands; while in hysteria, they escape and avoid all imperatives, turning situations in which the person has to comply to certain rules into an occasion of escape or disrupt the state of things (Lacan 1956). The “renegation” of the law in perversions has clinical consequences of persistent violation of rules, whether littering in public or flashing people on the street. The more complicated relation to such a law is the one that appears in psychosis, in which the law is forcluded, meaning it never had an inscription. Here, there was never a constitution of an internal regulatory instance also is in charge of an analysis of reality (Freud 1923, 2001), and therefore, norms and rules can emerge from internal drives, undistinguished from external demands, as the way in which the whole world is experienced has been defined differently.

In all, psychoanalysis has contributed to understanding how constitutive or founding a law can be for psychism. But while it shows where laws and our relations to norms come from, the rigidity of claiming the solutions are universal does not take into account the people’s life course or the contexts that change and in which people develop.

While there might be “styles” or abstracted forms of dealing with norms, specific social situations change and how we view the world also changes, making it difficult to speak of universality. Social situations, demands, and expectations vary, and these general styles, as they come from an internalization of social materials, might also change.

The Development of Rules and Norms

In developmental psychology, some scholars have tried to understand not the social construction of norms or their psychological roots, but their emergence and development in people’s lives across time.

Piaget’s was concerned with the construction of rules in children’s games (Piaget 1932). For Piaget, the child will accept a new rule in a game because he thinks that he has discovered a pre-existing rule – a rule pertaining to the established world of rules by the “Word of the Adult” (1932, p. 45). The child’s encounter with a new situation necessarily carries the weight of interpretation from his or her whole “moral life” (Piaget 1932). This means that whenever encountering a new object, game, or situation, this experience is made on the basis of the fact that the world is “morally” organized: that there are some things which we can and cannot do, some things which are right and wrong, in one word, the world is normative (Valsiner 2018). There is an initial identification of what is (the real) and what must be (the normative) (Piaget 1981).

More generally, Piagetian and post-Piagetian approaches analyzed the role of conflict for norm construction or change (Zapiti and Psaltis 2012). These authors show how multiply operating norms can enter into contradictions. A little girl might usually play under the norm that “knights are characters for boys” but when playing knights against monsters, she might consider not abiding by that norm in order to avoid being the monster as “the ugly character” or “on the losing side.” This might be a way in which flexibility in our relations to the norms is introduced.

From the sociocultural perspective, Lev Vygotsky (2016) was also concerned with norms, and he considered them behavioral

rules, which he calls “don’ts.” These can be social (interdictions), physical (things which go against physical rules, like lighting a match a second time), and biological (the fact that we cannot touch fire because we will get burnt). He argued that these diverse “don’ts” eventually combine in a single “situational don’t,” which can be understood as a barrier blocking the emergence of a specific action within that situation. Thus, when a child pretends to fly on a broom with a stick, there is a temporary suspension of a physical “don’t” – the child is not “actually” flying – but a social “don’t” marks the stick is not a horse but a broom as the child could equally be playing with a broom to ride a horse or a magic broom.

Winther-Lindqvist (2009) presents these authors’ approaches as considering rules as either prescriptive or sociocultural practices. For Piaget (1932), rules would be prescriptive regulations, whereas for Vygotsky, they are defined as sociocultural practices, indicating that “all social life and human interactions are governed by implicit social rules” (Winther-Lindqvist 2009, p. 22). This distinction does not appear to be mutually excluding, as norms can be socioculturally defined as well as function as prescriptive. I will now consider this sociocultural definition.

The Social and the Psychological

If we consider norms are sociocultural and psychologically defined, I propose to review and adopt the sociocultural perspective for their understanding. Guided mainly by a processual interest to understand change, this approach allows looking at the dynamics of passage from the social to the psychological level at which norms operate, and vice versa.

As a discipline, cultural and sociocultural psychology is concerned with studying human development as a social and cultural process (Cole 1996; Valsiner 1997, 2000, 2019b). One of its core premises is that this takes place through social guidance (Valsiner 1997, 2014; Zittoun et al. 2013). Children learn to manipulate a spoon and avoid plugs, parents come to

know how to speak to teachers and teenagers starting university discover how to write formal letters. These paths or ways of doing can be more or less imperative: a child can never touch a plug but a teenager can decide to provocatively write an informal essay to make a point. This process of social guidance has a fundamentally normative character (Valsiner 2018) and the normative weight of each action is defined within the situation and between the people involved.

Jaen Valsiner (2019b) claims that it is only by looking at how they are constructed, by people, in relation to other people and in a shared environment that we can understand why norms are fundamental for the functioning of any social group or collective. In this approach, norms are considered “cultural tools – made possible by sign mediation – that mediate the personal and collective movement towards the immediate future” (Valsiner 2018, p. 10). He further claims that all human psychological phenomena are normative (Valsiner 2018). It is considered to be what sets human systems apart from others and that “the normativity of the psyche is the developmental result of the interiorization processes from the materials available in the social environment – but not reducible to the latter” (Valsiner 2018, p. 9). Thus, from social normativity, the psychological normativity comes from internalizing, through the available material, a certain way of establishing relations between things – “when I see the sun comes up, I must wake up,” relating my looking at the sun, to getting out of bed.

Normative systems, at a social level, such as how one is expected to behave at work or brush one’s teeth, are considered to be socially crystalized (Zittoun et al. 2003) in everyday-life arrangements. The ways in which desks are set in an office and the types of objects that can be found – pens and paper, clips, computers, while no drinking glasses, party dresses or costumes – provide guidance of what things are or are not possible in each setting.

Formally, such social guidance is understood as made of semiotic constraints. Drawing on

Lewin’s (1936) model of fields of possible movement, Valsiner defines constraints as what creates partitions in a field of otherwise indeterminate possibilities (Valsiner 1998, p. 50). In that sense, norms are derived from constraints creating the “bounded indeterminacy” of developmental processes: they create directions for development, which are not imposed, but orient the infinity of possible forms. Norms are then generalizations from the repeated encounters with such constraints and can be defined as emerging configurations or sets of relations.

But norms are not simply there: they are constructed through experience. By playing, children test their limits, explore their boundaries and appropriate them depending on their consequences. Through imagination, adults engage with their transgression, their enforcement in an unfair situation or their transformation to avoid a social catastrophe. More so, through thinking, arguing, discussing, people give form and transform statements and scenarios. We can engage with a foreign world while sitting in a small windowless apartment and then feel better about our confinement, or yet decide to breach it and leave. These are processes that can explain how they change and emerge both at a social and a psychological level – and they have been a central part of sociocultural psychological research (Valsiner 2019a).

Norms and the Possible

Across the perspectives revised, I tried to show that authors always distinguish between a social and a psychological level at which norms function. Secondly, the focus on different questions in the authors’ propositions can be read as giving rise to static or dynamic depictions of how norms emerge and define what is possible. The definitions and classifications provided in anthropology (Levi-Strauss 1949; Malinowski 1926), philosophy, legal studies (Kelsen 2003; Nino 2013; Searle 1997) and social psychological research (Cialdini et al. 1991) specify which

kinds of norms exist but open up the question of their change and emergence. Social, cultural, and developmental psychologies (Valsiner 1997, 1998; Zittoun et al. 2013) as well psychoanalysis (Freud 1923; Lacan 1956, 1958) start from a processual outlook asking first about the psychological processes that allow their construction. Yet, for some of these authors, the possible appears to be defined by the law and the norms. They also determine what is impossible, what is thus sanctioned, leading to a rigid understanding of possibilities that do not appear to be open for change.

From a sociocultural perspective, we can articulate the twofold existence of norms and the processes that allow their construction. Socially, norms guide our behavior; psychologically, they form the way in which we think, feel, and speak. They become the points of reference from which we experience our lives and shape our future. But if the sociocultural norm merely guides what is psychologically reconstructed, and in specific situations, then there appears to be a large margin of freedom in our relations to them. The possible can be played with and imagined: children alter and change norms in imagined scenarios to push the limits of the possible; adults fantasize and imagine plays on norms; forms of social participation such as direct democracy allow people to create initiatives that question the norms underlying the laws, and proposing new ones – such as the instauration of women's right to vote. These engagements both define and redefine what is possible, moving and transforming its boundaries.

Every time a norm is constructed, reality is actualized in a certain way, and possibilities reorganize. What we consider allowed also defines fields of possibilities. We can engage with such possibilities, either without realizing them or by changing the current state of things. We can explore the possible, alone and with others, and this exploration might show us some possible paths, further changing current conditions, and might lead to also generalizing new norms, in an intertwined spiral of norms and possibilities.

Novelty

Maria Regina Brioschi

Department of Philosophy, University of Milan, Milan, Italy

Abstract

Novelty, defined as the quality of being new, has always been associated with a vast range of phenomena which had never existed before. The concept is of particular relevance especially in the fields of science, technology, and art, because they mutually deal with **discovery**, **innovation**, and **invention**. As it is apparent, the three disciplines mutually share the importance of creative processes, which lie at their very core. For this reason, the main investigations on novelty, both theoretical and empirical, from the twentieth century onward have mainly been carried out by philosophical and psychological studies related to creativity. Novelty indeed represents one of the fundamental criteria of **creativity**. Accordingly, this entry (1) begins with a general, phenomenological description of novelty, (2) points out the current relevance of novelty, (3) focuses on its history by providing a theoretical framework for its understanding, (4) explores different empirical researches and cognitive models of novelty elaborated hitherto, and (5) illustrates the fundamental relation between novelty and the possible.

This research was founded by the Department of Philosophy “Piero Martinetti” of the University of Milan under the Project “Department of Excellence 2018-2022” awarded by the Ministry of Education, University and Research (MIUR).

Novelty · Originality · Irreducibility ·
Potentiality · Process · Emergence · Creativity

Phenomenology of Novelty

In mundane experience, novelty is apparently a very common and widespread phenomenon, emerging at multiple levels of personal and social life. There are many examples of it, insofar as people frequently choose the adjective “new” to denote happenings, things, ideas, or whatever they were not acquainted with before: “a new book!,” “a new house!,” “a new pair of shoes!,” “a new job!,” “a new blossom!,” “a new baby!,” but also “a new hypothesis!,” “a new masterpiece!,” and so forth. In each case, “new” means that the object under observation is *unprecedented*, and this character is valid both for “natural” products, such as plants, animals, and so forth, and for “cultural” products, that is, what results from deliberative acts to impress a new form onto some previous material, such as manufacturing products, buildings, and so on. Among cultural products, new ideas are harder to define, because it is more difficult to establish to what extent the contents included in new ideas are old or genuinely new. In these cases “new” does not merely indicate something *unprecedented*, nor something *unusual*, but also something *original*.

The term **originality**, used as a quasi-synonym, reveals that novelty, together with its proper difference and rupture from the past, at the same time requires a point of comparison, a reference, or a certain **perspective** and a consequent appropriateness. To sum up, for a novelty to be such, it must always be *relevant* in some respect and for someone. For instance, in the cases of “a *new (original)* model for explaining something,” or of “a *new (original)* strategy for solving a problem,” it is implicit that the model/strategy is not only never stated before but is especially relevant for someone in achieving a definite goal. Stated otherwise, a certain discovery makes a new finding emerge, but the only way to designate that

finding as “new” is to make a comparison with other findings. This may be called the *relative* or *perspectival* character of novelty. It is often overlooked but can be found in all novelties.

The paradoxical nature of novelty lies exactly at these two antithetical points: that it is *unique* and *unprecedented* and at once *relative* and *perspectival*. Every novelty represents a discontinuity in a continuity, and for this paradoxical structure, empirical research on novelty is still exiguous. Finally, as the examples have already demonstrated, novelty is usually conceived as a *result of a process* or multiple processes, but irreducible to them, no matter whether they are natural, social, or cognitive.

Current Multidisciplinary Relevance

At the level of scientific research, novelty is viewed as a pivotal or prominent element in at least three fields. (1) Above all, novelty is related to the field of aesthetics, art, and, more recently, “creativity studies,” because it is regarded as an intrinsic characteristic of *creativity*, which artworks carry within themselves. As Gilles Deleuze sharply notes, “novelty is the sole criterion of any work of art. If you don’t feel you have seen something new, or have something new to say, why write, why paint, why shoot a film?” (Deleuze 2006, p. 217). Even more radically, **Ernst Bloch** underlines the profound relationship of works of **genius** and novelty, emphasizing how every great work of art “still remains [. . .] impelled towards the latency of the other side, i.e., towards the contents of a future which had not yet appeared in its own time” (Bloch 1995, 1, p. 127). Furthermore, the importance of novelty in art and its role in **creativity** has been accentuated since the 1960s by the continuous growth of advertising and media, which enlarge the boundaries of creativity and enrich its studies, especially in the fields of psychology, cognitive science, and neuroscience.

(2) Secondly, novelty is associated with technology and science, and more specifically with scientific progress. From the very beginning, scientific **inventions** have marked the appearance of mankind on Earth (cf. Plessner 2019),

determining as indissoluble the evolution of humanity and technology. To see how they both develop together through time, it is sufficient to consider that the distinction between Paleolithic and Neolithic human beings is based on their different technological **inventions**.

More broadly, all of the history of **science** illustrates the power of novelty under the guise of discovery. Something new is detectable in every single discovery in the history of sciences, and in like manner it can be singled out in every single process of scientific research. As Thomas Kuhn underlined, novelty constitutes the core of every paradigm change, of every scientific revolution (Kuhn 1996, p. 52). Moreover, in the past two centuries, biology has probably been the most stimulating science for thinking about novelty, especially **Evolutionary Biology** and **Epigenetics**. Overall, Charles Darwin's **evolutionary thought**, from its very beginning, has been posing a challenge to the modern (Western) mind-set, because it points out that nature is not of a fixed, immortal kind; rather it is dynamic, ever-changing, and in development (cf. Mayr 2004; Blitz 1992). Accordingly, the more physical and biological sciences improve their understanding of this dynamic and open structure of the universe, the more science theorists and philosophers must address questions like: "What categories are more adept for describing those substantially new changes that are indicated by a vast number of scientific results?"; "Can we actually speak of novelty?"; and "How is it possible for something new to appear?." The next section will show how twentieth-century philosophy has addressed those questions.

(3) Thirdly, novelty represents an issue of public interest, for ever-developing pluralistic societies, and the new challenges arising thereof (for instance, climate change or the new COVID-19 emergence), constantly require new measures, policies, and laws. The social and political constructions of the past, both at the international and national levels, continuously need modifications and innovations under the pressure of current challenges. As Giovanni Maddalena and Fernando Zalamea suggested, "Perhaps due to the period of international crisis, appeals to

creativity multiplied in any field. Sure enough, when the status quo cannot grant welfare conditions anymore, something new is needed" (Maddalena and Zalamea 2013, p. 6).

Therefore, on the one hand, the salience of novelty seems undeniable; on the other, as soon as one begins to discover how relevant it is, it becomes clear how difficult it is to capture the essence of novelty, to define it properly, and to scrutinize analytically it. It is as easy to recognize, as it is difficult to explain. For this reason, novelty can be regarded, both in everyday experience and in a vast number of disciplines, as "an indispensable concept and a serious problem" (North 2013, p. 5). Accordingly, it is first and foremost necessary to trace the history of the concept and to provide a theoretical framework within which novelty can be finally admitted and comprehended.

History and Theoretical Framework

The word "Novelty" – originating from the French *nouveauté* – is not widespread or frequently used in English. Its invention is quite recent, and the first written proof dates back no earlier than the fourteenth century. Nonetheless, the adjective is widely circulated, and, in this case, almost all Indo-European languages share the same root of *new*. Furthermore, in English, as in many other languages such as Ancient Greek, *new* and *now* come from the same root (cf. D'Angour 2011, p. 19), but this temporal association of novelty to the present will be clarified in the last section.

Beyond the specific, different, linguistic expressions of novelty, its adoption as a technical word and a theoretical concept in philosophical and scientific debates is even more recent, since it can be situated between the end of the nineteenth and the beginning of the twentieth century, and it became a topic of widespread discussion during the 1920s (cf. Brioschi 2020, pp. 175–80). As Stephen Shaviro states:

The concepts [of creativity, novelty, innovation] (or at least these words) are so familiar to us today [...] that it is difficult to grasp how

radical a rupture they mark in the history of Western thought. In fact, the valorization of change and novelty, which we so take for granted today, is itself a novelty of relatively recent origin. Philosophy from Plato to Heidegger is largely oriented toward *anamnesis* (reminiscence) and *aletheia* (unforgetting), toward origins and foundations, toward the past rather than the future. (Shaviro 2009, p. 70).

Before focusing on the very young history of novelty, it is first necessary to recognize the reasons for the absence of “novelty” in previous cultural debates before the nineteenth century. To determine them properly, a distinction must be drawn; the issue of novelty can be tackled from two different perspectives: ontological and epistemological. The first addresses questions like: “Does something new really exist?,” while the second: “Can one know something new?”

On the ontological level – and apart from Christian theology and the dogma of *creatio ex nihilo* first advocated by St. Augustine (North 2013, p. 36) – from Parmenides onward, novelty has not been explicitly considered because of the acceptance that nothing comes from nothing (*ex nihilo nihil fit*, cf. Mourelatos 1981). For being is and nothing is not. This viewpoint especially entails an idea of being and of the cosmos as fixed, static, and unchanging. Indeed, given this general framework within which traditional metaphysics arose, no question about novelty could have been posed. At most there was room for changes, conceived merely as slight and superficial modifications of antecedent configurations of things. On the whole, the stance of Western philosophy until the nineteenth century finds a concise expression in the words of the well-known motto from Ecclesiastes: “nothing new under the sun.”

On the epistemological level, in a sense the problem of novelty connotes the perennial problem of knowledge, which was formulated by Plato and is known as one of *Meno*’s paradoxes: “How can I know something that I didn’t know before?,” that is: “How can I know something new?.” Notwithstanding, novelty has been basically banished until the end of the nineteenth century. As Carl Hausman suggested with reference to creativity

(Hausman 1975, p. 2–17), the reason lies in a rationalistic conception of **knowledge** (and **reason**), such that nothing which lies outside of reason’s boundaries can be admitted. In this regard, Friedrich **Nietzsche** pointed out that “rational bias forces us to postulate unity, identity, permanence, substance, cause, materiality and being” (Nietzsche 2007, p. 19), and everything that exceeds such categories was condemned to mere appearance. As a consequence, novelty – along with difference, **change**, accidents, becoming, and so forth – was repudiated and confined to the margins of philosophy (**Derrida** 1986).

The main factor that determined the huge shift in mind-set at the end of the nineteenth century is represented by Darwin’s evolutionary theses, which confer a new *status* to novelty and the possible. Since then, in fact, the natural world could no longer be explained as a set of static, immutable, eternal essences, and with those categories could neither be understood truth (Mayr 2004, p. 26–27). Some philosophers took up the **challenge** posed by Darwin by trying to provide a new theoretical framework, according to which knowledge and reality could be seen in light of the inalienable relevance of novelty, **change**, possibility, and creativity. This evolutionary stance was expressed at its best by Classical **American Pragmatism** (**Charles S. Peirce**, William James, John Dewey, and **George H. Mead**), **Alfred N. Whitehead**, Ferdinand C.S. Schiller, British **Emergentism** (Conwy L. Morgan, Samuel Alexander, Charlie D. Broad) in England, and especially **Henri Bergson** in France. In his masterpiece *Creative Evolution* (1907), **Bergson** was indeed the first who drew attention to novelty and posed it as a genuine, unavoidable, and essential problem of philosophy, both for ontology and knowledge (cf. Schiller 1921–22).

Since *Creative Evolution*, the accounts of a processual universe, within which novelty finds a place as a result of a process, although not reducible to the elements from which it derives, increased in number in natural sciences (cf. emergent evolutionary theories). **Dewey** states that novelty is the “emergence of unexpected and unpredictable combinations” (Dewey 1925, p. 281). In the human sciences, and especially in

philosophy and psychology, studies committed to creative, cognitive processes began to proliferate. These studies aimed both to find a proper logic of discovery (cf. **abduction**, Peirce 1992, 1998) and to examine the process of creativity in all its complexity, without limiting it to the solitary activity of an isolated mind, but understanding it as a multilayered phenomenon that stemmed from the dynamic interplay of the individual with others and with the environment. From the very beginning, novelty was firmly associated with creativity. **Whitehead**, for instance, defines creativity as “the principle of novelty” (Whitehead 1978, p. 21), and this connection between novelty and creativity remains of utmost importance today.

Research on Novelty

Research on novelty can be divided into two different kinds: (a) *not-creativity-related*, when the conditions and characteristics of novelty are examined *per se*, and (b) *creativity-related*, when novelty is approached as a distinctive feature of **creativity**.

- Novelty Categorization Theory (NCT) (Förster et al. 2010) is committed to predicting when people perceive events as novel and how these new events are processed, thereby relating the perception of novelty to the broadness or narrowness of the mental categories in use. The other main research, from either group (a) or (b), although admitting that novelty is a result that emerges from various processes (from the merely material or productive, to the artistic, organizational, etc.), in fact limits novelty to as a result of *cognitive processes*, namely, as **mental construct**. Within this context, one of the most systematic research projects apart from creativity studies comes from the economist Ulrich Witt, who developed a **cognitive model** for novelty and explicitly differentiated its production from the creative act (Witt 2009, p. 315). Overall, by adopting a procedural approach, Witt shows that:

The creation of new cognitive concepts (ideas, imaginings) involves two operations. One is a generative operation that produces new (re-) combinations of elements. The other is an interpretative operation by which the new (re-) combination is integrated into a newly emerging or a more general already existing concept. (Witt 2009, p. 313)

According to Witt, the generative operation, which is the **recombination** of elements in accordance to some conformity or similarity criterion, can be externalized mechanically or electronically, while the interpretative operation always needs the medium of the human mind. Furthermore, this two-folded model makes it possible on the one hand to connect the epistemic status of novelty to the inductive characters of operation and, on the other, to distinguish *ex ante* between different degrees of novelty. As a result, it is affirmed that the degree of novelty is minimal “if the generative operation is known and the interpretative operation is trivial in the sense that the meaning of all its possible outcomes is known beforehand” (p. 318) and becomes maximal when “the generative operation is not known and no constraint can be imposed on the outcome of the interpretative operation” (p. 319). This kind of *not-creativity-related* approach shares with the *creativity-related* one the basic assumption that the production of novelty, or more broadly creative process, does “not create something out of nothing; it uncovers, selects, re-shuffles, combines, synthesizes already existing facts, ideas, faculties, skills” (Koestler 1964, p. 120).

(b) In *creativity-related* studies, empirical research on novelty has seldom been carried out, although from the very pioneering studies novelty is designated as an essential requirement of creativity together with effectiveness (from Guilford 1950 onward, cf. Runco and Jaeger 2012, p. 92). First, this is generally due to the elusive and paradoxical character of novelty, which is difficult to enclose in a linear definition. In this regard, it shares to some extent the same fate of creativity, inasmuch as the definition of creativity, far from being universally stated, is continuously modified and rephrased by research advancements and the different approaches they adopt. Second, the limited numbers of studies on novelty is justified by a

fundamental problem of method. As Runco and Yoruk recently said, “novelty can make **measurement** a challenge. Most tests and measures present a task or ask a question and compare the answer to norms or expectations. This is not possible when the test is designed to measure originality or novelty” (Runco and Yoruk 2014, p. 1).

Nonetheless, in the last decades, the flourishing of psychological and neuro-cognitive studies on **divergent thinking**, and related creativity tests, has reinvigorated the attention drawn to novelty and allowed new, divergent paths of inquiries. On the one hand, the role of novelty in creativity has been clarified in more detail, and two studies demonstrated how novelty “enhanced divergent creativity, but inhibited convergent creativity” (Gillebaart et al. 2013, p. 283). On the other hand, there have been many efforts to study the **emergence** of novelty as stemming from the interaction between personal and socio-cultural dimensions, because the label “new” is assigned at the end of both a judgment process and a social comparison (cf. Glăveanu and Gillespie 2015, Burns et al. 2015, Miettinen 2006, Liu 2000). Within this horizon, for instance, the essential role of constraints in generating novelty has been highlighted and tested as a strategy to augment novelty (Stokes 2005, 2009). Finally, from a bio-psychological approach, a conceptual model of the Novelty Generation Process (NGP) has been developed. This model aims at rendering the process of novelty as a whole, by making:

clear conceptual distinctions between the seeking for novelties, followed by the finding of a novelty and transforming it into a product visible to others, and finally innovative performance, which stands for the social recognition that the producer of a novelty can receive in this world. (Schweizer 2006, p. 167)

Therefore, this model presents the generation of novelty as composed of three phases: (i) the process of **novelty-seeking**, followed by (ii) creativity, divided in turn into two processes (novelty finding and production of novelty), and (iii) finally an innovative performance that

presents a product to a determined social environment.

Novelty, the Possible, and Creativity

As the phenomenological description, the theoretical framework, and the analysis on current empirical research tacitly suggest, novelty maintains a privileged relation with the realm of the possible. On the whole, novelty represents the threshold where possibility enters into the world. Novelty actualizes possibility without exhausting it.

From a descriptive perspective, novelty is *the impossible become possible*: “the impossible” because it cannot be predicted or foreseen on the basis of previous elements and “*become possible*” because it embodies possibility, and revealing it opens future horizons that were closed up to that moment. Novelty, understood as the opening of **possibility**, emerges at two different levels: in the interplay of the individual and the environment (both natural and cultural) and in the intersection of present and future.

With regard to its peculiar temporality, novelty is indeed *the future made present*. In this sense, novelty always rests in the present dimension, as the etymology somehow adumbrates through the common root of **now** and *new* but broadens its limits by pushing them toward the future. At the same time, for the “relative” character of novelty, revealed in both phenomenological description and empirical research, novelty re-creates the past. Novelty emerges in the present but is endowed with the power of redefining the past. So not only something is evaluated as new in comparison to old things, but novelty makes it possible to see old elements as new, thereby revealing possible scenarios that were hidden before the novelty appears. This feature of novelty is easily detected in the history of science, such as when a new discovery is made, or, in daily experience, when a new happening or idea allows us to reconsider and reinterpret past events under a new light. As **Mead** states, the happening of novelty in the present always “becomes a history and a prophecy” (Mead 1932, p. 21). Because of this essential

relationship between novelty and the possible, it is easy to see that the most feasible path for cultivating novelty is to enhance creative processes, no longer understood as individual, isolated, or mental process but as issuing from the dynamic interplay of different agents and temporal dimensions. Accordingly, novelty also enlarges our understanding of the future. The future is no longer the mere continuation of the past or the mechanical development of previous elements; it cannot be merely anticipated through **imagination**. Imagination envisages future possibilities; novelty creates them.

Conclusions

The phenomenon of novelty is well-known in ordinary experience: easy to recognize, harder to define. It plays a crucial role in creativity because it represents its vital ingredient along with value. Accordingly, it is a pivotal factor in all fields where innovation and creative processes are essential, such as art, science, technology, economy, and politics. Yet, the relevance of novelty, together with a theoretical discussion of its implications, is quite recent in the history of philosophy. As a consequence of the impact on philosophy of Darwin's evolutionary theses, the relevance of novelty can be located between the end of the nineteenth and the beginning of the twentieth century. From its very beginning, novelty was defined as the outcome of a process, though irreducible to it; and it was precisely in this resistance to be absorbed by the past where its profound connection with possibility can be found. Over the past decades, research on novelty – especially in psychology – has tried to find strategies to enhance novel results as well as models which render the process of generation of novelty. Overall, these studies have mainly focused on proposing the process of novelty as a reformulation of previous elements, such as ideas or experiences, while more detailed research into novelty's relationship with the possible is still unexplored. The more this connection between novelty and possibility is investigated in the

future, the more it will be possible not to forecast novelty, but to encourage and increase its power of transformation.

Old Age

Tania Zittoun

Institute of Psychology and Education, University of Neuchâtel, Neuchâtel, Switzerland

Abstract

With the current demographic changes observed in most postindustrial countries around the world, long-standing representations and knowledge about “old age” need to be critically examined. In effect, old age has been either idealized, as the time for wisdom, or feared, as the period of senility. With their focus on development and professional activity, social science and psychology have long considered aging as a decline of physical and psychological capacities, a closing down of the possible. Such view has been largely reflecting negative social representations of the elderly, or “ageism.” A classical attempt to resist these negative representations has been to highlight older people’s activity and capacity to compensate losses and thus maintaining some possibilities open. However, such vision usually overlooks the social and cultural conditions of creating or dismissing the possible in people’s with older age. On the basis of such a critical analysis, an alternative proposition to resist negative representations is made here: old age may be a period in which the possible plays a unique

role. Aging is, after all, a life-course developmental process, and as such, the possible plays a central role in people’s lives; it is even more so in old age, where it becomes vital. In addition, old age confers people a unique position from which they can propose alternative possibilities for themselves and the world.

Definition and Synonyms

“The words ‘old age’ and ‘centenarian’ refer to a social representation of people based on age” (Balard 2015). In most uses, “old age” refers to an age associated with the time of compulsory retirement or pension – somewhere in people’s 60s. In the last decade, given the increase of life expectancy, a distinction has been accepted between the “third age,” or the young old, and the “fourth age,” the oldest old and centenarians. Usually, it is admitted that the young old – in their 60–80s – maintain most of their cognitive and physical capacities, while the old-old, over 80s, meet various forms of decline. Obviously, these distinctions are relative; depending on sociocultural background, gender, geographical location, or biographical specificities, there is a very wide variety in people’s experience of “old age” – admitting that

it currently refers to a period which extends in average 20–30 years in rich societies, that is, from a period corresponding to the social marker of retirement until death (e.g., Baars et al. 2013; Biggs 2001). The very term “old age” with its variations (elderly, seniors, etc.) has been widely discussed and debated. For the purpose of this entry, the notion of “old age” is going to designate this socially admitted period extending beyond average retirement age; as category, “old age” cannot be disconnected from specific institutions, in their sociocultural context. In this entry, the expressions “people with old age” or “older people” will be used interchangeably so as to question the static implicit of the notion.

“Old Age” as a Reduction of the Possible

The history of old age and aging has been done by many, whether historians, sociologists, or psychologists (de Beauvoir 1970; Hall 1922; Troyansky 2016). Once officially retired, both Stanley Hall and Simone de Beauvoir tried to summarize a wide range of literature, ranging from philosophy to anthropology, sociology, psychology, and literature, in order to understand their current situation. As older intellectuals and scholars, formerly active and socially acknowledged, they found themselves suddenly socially excluded and treated as non-relevant nuisances – with reduced possibilities, which they fought with their writing; both were deeply aware of the sociocultural nature of such conception of age. Their situation and enquiry reflect the two “master narratives” that historians identify (Troyansky 2016): one of progress, in which the extension on life expectancy brings better old age in current times, and one of decline, considering that it was better to be old in ancient times. Beyond changes in life expectancy and the social role and positions ascribed to older people across time and places, these narratives seem to reflect deeper, contrasting social representations of aging, which have also tainted psychological approaches (Radtko et al. 2016).

On the one hand, there is a long-standing tendency in psychology and gerontology to show the illness, physiological, and psychological decline of

older persons (Anderson and Craik 2017; Johnson et al. 2005). This tendency is also reflected by the long-standing negative social representations of aging and the elderly, as frail, ill, lacking the tonicity, and innovation capacity of the young – what has been called “ageism” (Angus and Reeve 2006; Nelson 2005). It is manifested in the progressive professional and social exclusion of older citizens and, in care relationships, in a tendency to infantilize people (notably through the use of “elderspeak,” Balsis and Carpenter 2006). From such dominant and widespread representation, old age amounts to a shrinking of the possible in people’s lives: their health and body reduce possible actions, their chronological age limits social relationships, their access to social participation is limited, and reduced cognition makes thinking beyond what is, impossible.

On the other hand, and especially with the development of life-course and lifespan approaches, there has been a strong trend emphasizing the continuity of life and the specificities of development in old age (Baltes and Mayer 1999; Schaie 2016). If there has been a movement to defend the progressive disengagement of older people from social life after their working career (Cumming and Henry 1961), others have emphasized the many activities in which people may or, even, should be encouraged engaging in (Fernandez-Ballesteros 2008). Most of this literature is anchored in the lifespan approach developed by Paul Baltes and his team on the basis of the Berlin Aging Study (Baltes and Mayer 1999) and their SOC model – the idea that development requires selection (of skills and competences), optimization, and compensation (Baltes 1997). Literature has since explored the conditions in which people with old age could maintain a good quality of life, notably by compensating losses, in terms of autonomy, health, and subjective well-being (Freund 2008; Lang and Rohr 2015). This gave rise to approaches promoting and supporting active, positive, and, even, “successful” aging (Bülow and Söderqvist 2014; Fernández-Ballesteros 2019; Fernández-Ballesteros et al. 2019; Freund 2008; Gergen and Gergen 2010). This second trend seems to admit that old age demands a transformation of the possible in the person’s life and development. Within this trend, and at time, to contrast with the medical emphasis of

some part of that research, various authors have tried to highlight the specificities of age; one line of studies has thus stressed that old age may be an occasion to develop wisdom, seen a capacity to address complex issues in a measured and nuanced way (Ardelt and Oh 2016; Staudinger 1999; Sternberg and Lubart 2001). However, beyond the variety of definitions and operationalization of this concept, it becomes clear that wisdom is not attained by all in old age, although people with old age tend to show more wisdom than young ones (Glück 2015).

Various criticisms have been addressed to both trends: their centration on a model of the working (male) adult; their emphasis on youthful and healthy functioning; their hidden agenda (healthy older people are “less expansive” at a societal level); and their hidden discrimination of “unsuccessful” aging and its possible effects on people (Baars et al. 2013; Radtke et al. 2016; Stenner et al. 2011).

In any case, representations and narratives of old age are deeply connected to a vision of the possible, or the impossible for people with older age. To examine this question seriously, and to go beyond common sense, the possible will be defined here as the sociocultural and psychological process of generating alternatives, or of maintaining open alternative modalities to what is, mainly through imagination and multiple perspectives: the possible demand modes of “as-if” thinking or experiencing, a tolerance of uncertainty, or an opening to the future (Epstein 2019; Glăveanu 2018; Josephs 1998). On this basis, to summarize what has been exposed so far, a first broad research trend considers old age as a period of progressive and necessary reduction of the possible, until death arrives; a second group of research rather considers that through compensation, it is conceivable to maintain some possible in lives or reduce its transformation into the non-possible. But these issues may not only be a matter of theoretical preference, or people’s good will; what is possible for people with old age is to a great extent socially and culturally defined and can be questioned. Hence, under what conditions are these possible, possible at all? And then, is there nothing to create, expect, imagine, and open up as new possible with age?

What possible may people with older age actually create?

Old Age, Society, and the Possible

A developmental and sociocultural perspective that considers historico-cultural transformations, the social and material environment in which people’s lives unfold, and their unique perspective invites us to consider more carefully the issue of old age and the possible. In effect, such perspective considers that the person’s conduct is deeply enabled, supported, guided, and constrained by bodies, social others, as well as material and symbolic arrangements (Brinkmann 2011; Brown and Reavey 2017; Cole 1996; Fuhrer and Josephs 1998; Gillespie and Zittoun 2010); it can thus draw on current studies in sociology, anthropology, or geography of old age.

There is a growing body of literature showing how societies themselves exclude and cut down the possible in older people. Anthropology, sociology, and history have largely shown that societies and symbolic systems can find extremely different ways of dealing with their older members, from exclusion and abandonment to careful inclusion and valorization of age (de Beauvoir 1970; Troyansky 2016). In industrialized and rich societies, there is a clear systemic tendency to exclude people with old age. The question of negative representations of older people (“ageism”) has already been mentioned above. In addition, in many countries, the system of retirement with its compulsory age limit tends to exclude older citizens from the public arena, or from participation in the *polis* (unless the rare members of Administration councils or politics). It also has to be mentioned that, until recently, housing facilities such as retirement homes and resorts proposed to older people were located out of urban centers. Finally, in many countries, the system of pensions or retirement puts older people in a state of relative poverty which, together with these other aspects, may prevent them from fully participating in social and cultural life (for an overview on social exclusion, see, for instance, Walsh et al. 2016).

On a smaller scale, it is clear that the environment in which people with old age live can support, or not, what is possible for them. Through their reconceptualization of the notion of care, social sciences have invited to consider the whole social and material environment participating in people's well-being. Close and distant relationships, formal and informal places, material arrangements, and temporal organization can all be seen as participating in the people's "landscape of care" (Milligan and Wiles 2010; Wang 2019); these can evolve as people develop their own trajectories (Kemp et al. 2013). In this sense, it may be worth considering the wholeness of older people's life situation: the settings in which their lives take place, the social representations and discourses they are exposed to, the cultural experiences they may have, and the social networks and the daily material and practical arrangements in which they live. A growing number of studies have examined the whole lifeworlds of older people, showing that place, social relationships, activities, and engagement can support the possible (such as Lieblich's 2014 study of a community of retired people next to a beach). Other studies examine smaller-scale arrangements that may support concrete, material, as well as symbolic possibilities: assistive technologies that enable people to feel safe enough to maintain their explorations of places (Cahill et al. 2018); urban arrangements which are more inclusive and facilitate social and cultural participation (Jianxi et al. 2018; Pan et al. 2018); new technologies that support transnational and intergenerational communication (Iannaccone 2015); or modes of housing that afford intergenerational exchanges and social participation (Jayantha et al. 2018; Labit 2016).

Conversely, it is important to document ways in which life conditions for older people can close down the possible. Above were mentioned various forms of social exclusion, social representations and discourses. In addition, there are concrete actions that limit the possible in people's lives. For instance, in a moving auto-ethnographic account, community psychologist Seymour Sarason described the poor conditions in which he was hosted during his final years in

an American nursing home, which can be seen as a slow erosion of the possible (Sarason 2011). Life conditions in the nursing home can be widely improved, turning these into places supporting people's interest and engagement even in very old age – a reflection done in many countries.

The Unique Possible of Old Age

Beyond a better understanding of the sociocultural production or reduction of the possible in older age, one also has to rethink the specificities of old age in what regard the possible. Even more, one can argue that the possible plays a key role in the life of older people, and their age also gives them a unique outlook on the creation of the possible.

First, the simple fact that people with older age have lived longer and have experienced changing sociocultural environments gives them a unique view on the past, present, and future. This argument has two aspects: to start with, it is likely that people who lived longer simply lived a larger variety of experiences from which they could learn and generalize (Zittoun and Baucal *in press*; Zittoun et al. 2013). Of course, this is somehow simplistic, as some younger people may have a very varied experience and some older person conduct their lives in a more repetitive way, preparing them less for change. The second aspect of the argument is more specific: only people who lived longer have seen, together with the psychological experience of their life, the sociocultural context evolve for so many years (Hviid *in press*; Zittoun and Baucal *in press*). Hence, having seen and experienced sociocultural transformations and their impact on societies, their lives, and these of others, people with older age may as well draw on their knowledge of the past and society as resources to question the present and to open new possibilities for the future. This kind of knowledge has thus been coined as "phronesis," or practical wisdom (Hviid *in press*; Trowbridge and Ferrari 2011). On the basis of their unique reading and experience of the past, people with older age may, in some conditions,

actually see and imagine alternative possible for society.

Second, at a more psychological or subjective level, many authors have questioned the actual experience of aging and the many ways by which people make sense of their lives, past and present. Interestingly, a wide range of approaches tend to emphasize the fact that living a meaningful life with older age actually depends on one's relationship to possible futures. Narrative gerontology, examining people's life's narratives, has shown the importance of "narrative openness" in old people, even in retirement homes (Gubrium 1995, 2011). In contrast, people manifesting "narrative foreclosure" – that is, who are not able to organize their narrative toward a future – tend to give up on living (Freeman 2011). Psychoanalytical approaches to the very old and people with terminal illnesses have emphasized the core role of desire – desire to live and desire for others and things – in people's lives: this only drives people toward the possible and the future (Quinodoz 2008; Villa 2010). Interestingly, lifespan and more cognitive approaches have shown similar phenomena: in their reading of the Berlin Aging Study, Smith and Freund (2002) realized that both old and very old respondents produced a certain number of hopes for their futures – as much as fears – and that, although some of these were constant, most of them were for a good part dynamic. These hopes were not only oriented toward compensating losses (e.g., health related) but actually toward creating new possibilities for the self. Based on neurocognitive evidence, Sakaki and colleagues (Sakaki et al. 2018) have shown that curiosity and openness to experience may be good predictors for cognitive health and well-being. These evidences point to the same direction: it seems to be key, for older persons, to maintain an openness to what is to come, by being engaged in the present and toward alternative possibilities, and possible futures; this tension toward the future of course draws on past, personal, embodied, relational, and also world-related experience. In this sense, development in older age seems clearly to be deeply related to a form of life creativity, fed by imagination. An important question is thus at what sociocultural

and relational conditions can such imagination but preserved and supported (Zittoun and de Saint-Laurent 2015; Zittoun and Sato 2018).

This leads us to a third form of experience of the possible for older: the actual transformation of these conditions. Indeed, if older people may gain a deeper understanding of their world and maintain openness to the possible, many also understand that their sociocultural world limits the possible for them and yet also that only by changing the world they can turn the imagination of the possible into the actual (Zittoun et al. 2020). Such realization demands a radical redefinition of old age, the role of old age in our society, and what is appropriate or not for people with older age – a poignant call made by de Beauvoir herself (de Beauvoir 1970). Interestingly, reading Stanley Hall and Betty Friedan's writings on aging, Woodward (2002) justly notes that these authors had to deal with their anger of being socially excluded. She also questions the discourse on "wisdom": supporting positive aging and wisdom is in some way, she argues, to ask older people to come to terms with their situation and exclusion; it demands acceptance of the status quo. In contrast, one could support anger in old age: only anger could promote revolt and change and open new possibilities for old age (Woodward 2002). Thus, it is important to observe that groups of older people have started to organize themselves into political activism, under revealing names such as "raging grannies", "grandparents for asylum" or "grandparents for climate," claiming that their age and experience lead them to some specific expertise. They also emphasize the freedom age gives them: without not much to lose, out of social norms, they gain a freedom of speech and action which enables them to become active in social transformations and in the creation of new possible (Caissie 2011; Hviid *in press*).

Summary: Supporting the Possible and Old Age

Older age takes an increasing importance in societal debates. The two dominant narratives about old age are, on the one hand, a story of bodily

decline and closing down of possibilities and, on the other hand, a narrative of compensation of losses likely to maintain the possible. A more critical look brings two other arguments to the fore: first, that the possible in old age is dependent on social, material, and symbolic conditions, which can easily be bettered, and second, that the possible plays a core and vital role in old age. It may be even argued, first, that the possible plays a vital role in people with older age and, second, that older people's perspective on the world may actually enable them to uniquely participate to the creation of new societal possible. How can we – as society, scientists, or practitioners – support the possible in old age? This demands both empirical work and theoretical new conceptualizations of human development in general and old age in particular. In effect, conceptualizing human life in its sociocultural environment, together with recognizing the actual social, material, and symbolic conditions that participate in the closing down or opening up of the possible for people with old age, calls for a radical transformation of our understanding of what old age is. We have to move from a vision of old age as, for the worst, reduction of the possible, or for the best, and as maintenance of the possible, to understand the uniqueness of the possible in life with old age.

Open-mindedness · Intellectual virtue ·
Gullibility · Dogmatism

Introduction

What is open-mindedness? Is it a positive trait that we should acquire and cultivate? On the face of it, these questions seem to have straightforward answers: To be open-minded is to be receptive to ideas that are novel or differ from one’s own. Moreover, such a receptivity appears to be unqualifiedly good in that exercising it helps to improve one’s epistemic status, whether by removing false beliefs and acquiring true ones or by expanding one’s understanding. Consider two people, one of whom is open-minded and the other is not. Intuitively, the person who is open-minded – that is, the one who seeks to expose herself to new ideas and to consider them – seems to stand a better chance of obtaining intellectual goods than the one who is not. Intuitive and appealing as these answers may be, they are also simplistic and incapable of addressing the two opening questions, which are deceptively complex and difficult. For one thing, common misconceptions abound about exactly what it means to be open-minded. For another, serious objections have been advanced to show that open-mindedness might not be as rosy a trait as it is commonly assumed. This entry summarizes recent work in philosophy on the topic of open-mindedness, with a focus on how philosophers

have answered the two above questions. It opens with an examination of some misconceptions held about open-mindedness, followed by a review of some contemporary theories of the character trait. After looking at some recent challenges that have been raised against open-mindedness, as well as some responses to them, the entry concludes by discussing how open-mindedness is relevant to the study of the possible.

What Open-Mindedness Is Not

Recent literature on open-mindedness in philosophy has revolved around two questions: (1) What is the nature of open-mindedness? and (2) Is open-mindedness a character trait that should be cultivated and exercised? These questions are, of course, related: Whether or not we should practice open-mindedness depends on what it entails to exercise the character trait, specifically what it commits us to do. There are misconceptions, however, that obstruct a clear understanding of open-mindedness. One misconception is that open-mindedness is equated with the mere **openness** of the mind. Accordingly, an open-minded person is always receptive to new ideas and willing to give them serious consideration, as if her mind's gates, so to speak, is always open to any incoming idea. Any attempt to bar any idea from entry would be a sign of her closed-mindedness.

A second misconception is that a person is open-minded only when she has not made up her mind about a specific issue. In other words, open-mindedness is perceived to be incompatible with a person's having firm and entrenched beliefs. The reasoning behind this misconception is that if a person has already made up her mind on a subject matter, she takes her beliefs on it to be true and does not entertain any doubts about them. She thus lacks any reason to be open-minded toward other ideas. To do otherwise would imply that she thinks that these other ideas may be true, which in turn suggests that she has doubts about her firm and entrenched beliefs (e.g., see the discussion in Adler (2004) and Riggs (2010)). According to this misconception, open-mindedness therefore applies only when a person has not thought

much about or decided on an issue (e.g., see Gardner 1993).

A third misconception is that open-mindedness seems to demand, at least from a pre-theoretical way of thinking about the character trait, both receptiveness to novel ideas and acceptance of them. It is not enough just to consider novel ideas. If rejection comes after serious consideration, it is still seen as closed-mindedness. Clearly, it is unreasonable and unwise to make indiscriminate embrace of all novel ideas a common practice.

What Open-Mindedness Is

Philosophers have rejected all of the above misconceptions. The background assumption they employ in discussing open-mindedness is that it is an intellectual virtue (e.g., see Baehr 2011; Kwong 2016, 2017; Riggs 2010). Roughly speaking, a character trait is considered an intellectual virtue when its exercise is conducive to the attainment of intellectual goods, such as truth, knowledge, and understanding. Its acquisition and cultivation require much effort on its practitioners' part, which is why a person can be praised for possessing a virtue and criticized for lacking it (or possessing the associated vice). Examples of intellectual virtues include intellectual courage, honesty, perseverance, humility, generosity, responsibility, conscientious, and open-mindedness. Following the neo-Aristotelian tradition, philosophers conceive of a virtue as flanked by two vices in practice, being too much (excess) or too little (insufficiency) (e.g., Zagzebski 1996). In the case of open-mindedness, the vices associated with it are gullibility (or excessive open-mindedness) and closed-mindedness or dogmatism. Accordingly, virtuous open-mindedness occupies the middle between these vices, and denotes the disposition to exercise the character trait *appropriately*: One has to perform the right sort of intellectual behaviors at the right time, in the right contexts, and for the right reasons.

What are the intellectual behaviors distinctive of an open-minded person? Or, what is the unique characteristic psychology of open-mindedness

that sets it apart from other intellectual virtues? It is tempting to think of open-mindedness as constituted by a disposition to revise or give up one's beliefs when confronted with opposing evidence (see Hare 1979, 1985; Riggs 2010). Despite its intuitive appeal, philosophers have rejected this definition of open-mindedness. Wayne Riggs (2010), for example, has argued that this construal of open-mindedness makes it indistinguishable from rationality, which is a preparedness to revise one's beliefs in the face of contrary evidence. According to him, being rational is *not* the same thing as being open-minded. Similarly, being irrational is not the same as failing to be open-minded. The aforementioned disposition is not therefore a tenable definition of open-mindedness.

Other accounts have been proposed to discuss the characteristic psychology of open-mindedness. Riggs has argued that, in addition to the disposition to revise one's beliefs in the face of contrary evidence, an open-minded person exercises certain "habits of thoughts" (2010). In particular, the person has to cultivate an ongoing self-awareness of her biases and prejudices that may hinder his/her pursuit of intellectual goods, and to be vigilant in detecting their presence so as to minimize their effects. For Riggs, an open-minded person is someone who recognizes her own fallibility in these respects, and stands ready to consider alternative beliefs while reassessing her own in light of them.

Many accounts of open-mindedness, like Riggs's, implicitly assume that the trait applies mainly in cases in which there is personal conflict, namely, when a person's cherished beliefs are challenged and adjudication is necessary (e.g., Adler 2004; Hare 1979, 1985; Riggs 2010). An alternative formulation of open-mindedness comes from Jason Baehr (2011). Baehr points out that open-mindedness can also be exercised in cases beyond those in which a person's beliefs are challenged or require rational assessment. For instance, a judge has to exercise open-mindedness in adjudicating disputes that do not impinge upon her personal beliefs. At the minimum, she must hear the plaintiff's and defendant's arguments out with an open mind and remain impartial instead of rushing to make a premature judgment. Likewise,

a science student needs to have an open mind in order to grasp novel concepts, such as Einstein's General Theory of Relativity. In such a case, open-mindedness is needed not to make rational assessments but to make sense of drastically different ways of thinking. According to Baehr, these are also instances of open-mindedness. What they share in common, he notes, is that the subjects in them all "cognitively transcended" their default viewpoints so as to take up another in order to give it serious consideration (2011). Put another way, each had to temporarily suspend her usual way of thinking to make room for a novel one. Such a cognitive transcendence, for Baehr, constitutes the heart of open-mindedness.

A third account of open-mindedness has been proposed by Jack Kwong, who construes open-mindedness more broadly as a willingness to *engage* with novel viewpoints (Kwong 2016). For him, to engage with an idea is to make room for it in one's mind and give it serious consideration. Additionally, the type of intellectual activities required for engagement will be determined by the epistemic context. Some cases will call for evaluation and assessment, while others will merely involve attempts to understand. Following Baehr, Kwong agrees that open-mindedness extends beyond personal conflicts. However, Kwong differs in disputing that cognitive transcendence is always needed to give differing ways of thinking serious consideration. A person can come to see a different idea as true or false from *within* her own viewpoint. The principal rationale behind Kwong's account is that it addresses both virtuous open-mindedness and its associated vices: Dogmatic or closed-minded people tend to lack the willingness to engage with any different idea, and the gullible, only too willing to do so, but the virtuously open-minded tend to exhibit such a willingness only under suitable circumstances.

While the three accounts above (Riggs, Baehr, and Kwong) differ in terms of what constitutes the core of open-mindedness, they agree that the character trait requires that a person be disposed to give novel or differing ideas *serious consideration*. They also agree that a genuinely open-minded person must exhibit relevant intellectual

behaviors with the *proper motivation*: She must do so out of a desire or love for the truth and other intellectual goods. Thus, someone who gives serious consideration to novel ideas because she is motivated by fame and status can hardly be characterized as genuinely open-minded. Despite their individual emphases, all three accounts can perhaps be seen as complementary to one another to furnish a comprehensive description of open-mindedness (Kwong 2016): Kwong's as identifying the general disposition behind open-mindedness, Baehr's as discussing a key skill in engaging with (some) novel ideas, and Riggs's as highlighting some of the central reasons why an open-minded person would want to be so engaged.

Is Open-Mindedness an Intellectual Virtue?

Recall that open-mindedness is generally regarded as an intellectual virtue. Pretheoretically, it is considered a positive trait that people should possess. A main reason is that it is conducive to obtaining intellectual goods such as truth, knowledge, and understanding. Consider two people who are roughly equals in terms of intellectual abilities and knowledge, except one is open-minded while the other is closed-minded. Intuitively, it would seem that the former is more likely to access and acquire intellectual goods than the latter. By being disposed and willing to give novel ideas serious consideration and to reassess her own in light of them, the open-minded person stands a better chance of uncovering her false beliefs, acquiring true ones, and expanding her understanding. Conversely, a closed-minded or dogmatic person refuses to engage with any new idea or reevaluate her own beliefs and forfeits opportunities for acquiring intellectual goods.

This neat and tidy view of open-mindedness has recently been challenged by philosophers (e.g., Carter and Gordon 2014; Cohen 2009; Curzer and Gottlieb 2019; Fantl 2018; Ferkany 2019; Levy 2006). According to them, open-mindedness is not always conducive to the aforementioned intellectual goods. Some have even

suggested that it is an intellectual vice under certain circumstances. J. Adam Carter and Emma Gordon (2014), for instance, have questioned open-mindedness's relationship with truth, arguing that the two are not intrinsically connected and thus, open-mindedness does not guarantee that truth will be obtained. The lack of such a connection is especially troubling in cases where a person *already* possesses true beliefs but decides to give alternative ideas – false ones – serious consideration. Ideally, she would come to reject these ideas. However, she might not do so, especially when these ideas are deceptive and appealing, or so technical that the person lacks the relevant skills and knowledge to assess them. Undesirable consequences will include her swapping her true beliefs with false ones or being beset with open and unanswered objections. Either way, the critics point out, her exercise of open-mindedness can cause her to be epistemically worse off.

Further considerations have been adduced to show that open-mindedness can be a risky or dangerous practice. One is that open-mindedness is thought to incur the practitioner's commitment, as an active duty, to seek out opposing views to her own (Levy 2006), thus opening the door to false and deceptive views, or views that she lacks the requisite expertise to assess, and ending up in a worse epistemic situation. Another is that open-mindedness seems to be an inappropriate exercise in epistemically unfriendly or hostile environments. Descartes's hypothetical scenario of an evil genius comes to mind, wherein an all-powerful being is preoccupied with the task to deceive us to ensure that our beliefs are false. Other scenarios include living in a world where everyone lies or misleads, or where only books with factual mistakes are available. Under these circumstances, open-mindedness, far from being conducive to intellectual goods, is a sure way of losing them. While it is tempting to dismiss these scenarios as fanciful and far-fetched philosophical thought experiments, it should be noted that the world in which we inhabit may already be epistemically unfriendly and hostile. Consider social media platforms like Facebook that many people regularly use or abuse. Fake news, deepfakes, click bait, information engineered to be

misleading, and lies abound on such venues. To exercise open-mindedness on social media is therefore likely going to result in a loss of intellectual goods.

Critics of open-mindedness therefore have challenged the status of open-mindedness as an intellectual virtue. In their view, a virtue is a character trait that is supposed to be exercised across contexts. But certain contexts, like an epistemically hostile environment, are certainly unsuitable for exercising open-mindedness. To preserve one's epistemic integrity, these critics argue that it is better – even virtuous – to be dogmatic and closed-minded in such environments.

Against these criticisms, efforts have been made to defend open-mindedness. One strategy is to focus on the commitments of open-mindedness. A condition of what it means to be virtuously open-minded is to know *when* to exercise the trait. Baehr has suggested that a person should be open-minded when it is reasonable for her to believe that doing so stands a good chance of obtaining the truth (2011). For example, she may judge that the source or author of the opposing view is reliable and trustworthy, or that her own beliefs may be biased or unsupported by evidence. Were she to exercise open-mindedness under these circumstances, she would stand a good chance of improving her epistemic standing. By contrast, if she were aware that it was an epistemically hostile environment where truth was scarce and falsehoods and misleading claims were rampant, then she qua an intellectually virtuous agent should choose *not* to be receptive to novel ideas. The point is that her refusal to engage with new ideas under these circumstances would not suggest that she is closed-minded; she does not, after all, possess the disposition to dismiss novel ideas without a good reason. Rather, her refusal would be based on her judgement as a virtuously open-minded person that her being receptive in this instance would be highly risky. To paraphrase Riggs, she could refuse to consider these ideas *open-mindedly* (Riggs 2010). To be virtuously open-minded, then, is not just to be receptive to different ideas but also to have the

practical **wisdom** to know *when* to be so receptive.

A second way to mitigate the critics' worries is to emphasize another key feature of being open-minded. Advocates of open-mindedness all agree that it involves giving novel ideas *serious consideration*. A person who is receptive to novel ideas but only considers them in a casual manner can hardly be characterized as truly open-minded. Simply put, to give an idea serious consideration is to interpret and assess it thoroughly, attentively, objectively, fair-mindedly, charitably, diligently, and honestly. One must also have the relevant intellectual skills and capabilities for doing so. According to this line of defense, the virtuously open-minded person would have the resources to detect and screen deceptions and falsehoods from true ideas. That is, she would have the intellectual know-how not to be led astray from the path toward truth. While this is not a foolproof method – after all, human beings are fallible – defenders of open-mindedness claim that by giving novel or opposing ideas serious consideration, one could reap intellectual goods *more often than not*, and that in this sense open-mindedness is conducive to such goods.

A third way to respond to criticisms is to argue that virtuous open-mindedness only requires practitioners to be motivated in the right way, regardless of results. The discussion so far has assumed that open-mindedness is a reliable exercise in obtaining truth, knowledge, or understanding. Some philosophers, however, have elected to exclude this success as a condition for the possession of the virtue. James Montmarquet (1993), for instance, has pointed out that some of history's great minds (e.g., Aristotle, Galileo, and Newton) got things wrong though they had exercised traits like open-mindedness, perseverance, intellectual courage, etc. Despite the fact that they failed to acquire true beliefs and knowledge, they could still be praised for exercising those intellectual traits. This is because they did so with the proper motivation, namely, out of a desire and love for truth (and other epistemic goods). For philosophers like Montmarquet, proper motivation is sufficient ground for attributing these virtues to these

historical figures, even though they were unsuccessful in obtaining intellectual goods. Applying this defense to one of the critics' above worries, the person who is deceived by an evil genius but who exercises open-mindedness out of a desire and love for truth can still be praised as virtuous even if she does not end up with any truths.

Open-Mindedness and the Possible

Open-mindedness eschews intellectual limits and borders and thrives on the possible. Vlad Glăveanu has argued that to engage with the possible is to enrich and expand our experience of ourselves, others, and the world by “remembering the past, imagining the future, considering alternatives, anticipating problems, and continuously engaging in ‘as if’, ‘what if’ and ‘if only’ thinking processes” (Glăveanu 2018, 519). It is to go beyond how things actually are and to anticipate, imagine, **wonder**, and create **possible worlds**, selves, pasts, and futures. Open-mindedness plays a key role with respect to how we can move outside of the “**here and now**” for the possible. Consider someone who is closed-minded, that is, someone who refuses to engage with, or is not receptive to, novel ideas. She is stuck in her existing beliefs, interpretations, and explanations (about the world, self, past, and future), her usual ways of thinking, and her habits. Because her mind's gates are closed, she cannot conceive of and experience alternative ways for the world, herself, the past and the future to be. She shuts out possible epistemic goods, now broadly construed to include not only truth, knowledge, and understanding, but also interesting, creative, transformative **insights** and ideas. Only by being open-minded would she be free to embrace new possible ways of thinking.

Open-mindedness does not only concern our receptivity to the possible but also governs our conception of it. A person can be imaginative and creative, and easily inspired by novel ideas but fail to be open-minded. Even though she may be highly receptive to alternative views of how things could be, she can refuse to take them seriously or reject

them without justification in the end. Recall the two vices that accompany the virtue of open-mindedness: gullibility and dogmatism. Depending on which vice prevails, the consequence of failing to be virtuously open-minded is that her experiences of the world, self, past, and future would *not* be enriched by possibilities, real or imagined. What this suggests is that virtuous open-mindedness can play a *regulatory* role with respect to other cognitive traits or processes that are fundamental to our engagement with the possible. We can be as imaginative, anticipatory, or creative as we want to be, but unless we are truly prepared to take the thoughts and conceptions from our imagination, creativity, **anticipation**, and other cognitive processes seriously and if necessary, change our minds in light of them – both of these constitutive features of open-mindedness – we will not enhance our understanding and knowledge of ourselves, others, and the world.

Open-mindedness can regulate other cognitive processes or traits in terms of the possible in yet another way. As noted, an open-minded person is aware that she is fallible and her existing ways of thinking about the world, self, past, and future may be limited or mistaken. Her desire and love for truth, knowledge, and understanding motivate her to be receptive to novel ideas – that is, to other possible ways of thinking about the world, self, past, and future. However, not every novel idea will merit her attention and effort, for she will only consider those that she judges to originate from a reliable and trustworthy source or have a reasonable chance of being true. And when she does give ideas consideration, she does so seriously: To truly appreciate and grasp the novelty of these views, some of which may differ radically from her usual ways of thinking, she will need to recruit and employ resources such as her **imagination** and **creativity** in order to transcend her own default cognitive viewpoint. If after serious **inquiry** she deems an idea to have merit or be informative, she will incorporate it, either as a new belief or one that replaces a previously false or inferior one. On this positive account, we see that open-mindedness as an intellectual virtue can regulate cognitive processes relevant to the possible

in several ways: It prepares the mind to be in a state where it could be struck by *wonder* or readily *inspired* by external sources; it *inspires* a person to pursue certain unfamiliar avenues or modes of thinking; and it summons *imagination* and *creativity* in order to form or grapple with different perspectives.

The foregoing discussion suggests another dimension that open-mindedness can bring to the conversation about the possible. Although interesting work has been done to examine the cognitive mechanisms for engaging with the possible, and to identify the sociocultural factors that bring out and highlight differences in positions and perspectives, little attention has been paid to the *normative* side of such engagement. A relevant normative issue that arises in this context is the extent to which we should be open-minded with respect to the possible. We have already seen that a person can be *too* open-minded in that she is willing to consider ideas that she should not. She may, for instance, contemplate possible but misguided ways of understanding or reconstructing her past, resulting in her losing touch with reality or being self-deceived. Or she may imaginatively or creatively construct possible worlds with the potential that their realization may harm others. In these cases, virtuous open-mindedness demands that she refrain from these possible ways of thinking. Conversely, a person can also fail to be open-minded in that she refuses to consider any perspective or position that differs from her own. Such a failure is especially damaging and critical if it pertains to issues of social and moral significance, such as race, **gender**, and class. Under this circumstance, virtuous open-mindedness demands that she take certain possible ways of thinking seriously, ways that could expand her narrow viewpoints or correct mistaken ones. In sum, introducing open-mindedness can illuminate *appropriate conditions* under which a person should engage with the possible, conditions that pertain to morality, rationality, and truth. Virtuous open-mindedness prescribes that we open ourselves up to possible ways of thinking about the world, self, past, and future, and do so in a way that enhances and enriches our experiences in an intellectually responsible way.

Openness to Experience

Alexander P. Christensen
University of North Carolina at Greensboro,
Greensboro, NC, USA

Abstract

As one of the five major personality traits, openness to experience has been established as a fundamental factor of personality. Yet its history, and what it constitutes, has not always been clear. This becomes obvious when observing how the label has changed over the decades: from *Inquiring Intellect* to *Intelligence* to *Culture* until finally the consensus of *Openness to Experience*. This final connotation denotes people who are flexible and receptive to all experiential possibilities. It is this flexibility that perhaps most defines open people and enables them to be creative, establish complex worldviews, and probe the depths of human experience. Therefore, open people not only *see* more possibilities but also *engage* with them. This chapter starts with a brief review of the history of openness to experience that leads into contemporary conceptualizations. It then moves on to discussing research on the trait's associations with cognitive, perceptual, and behavioral outcomes. Finally, specific emphasis is placed on types of experience and how these may vary depending on people's characteristics of openness to experience.

Cognition · Perception · Curiosity

Definition and History

Openness to experience is a broad and complex trait whose definition has been contentiously debated over the years. The origins of openness to experience can be traced back to Cattell (1947), who used an intelligence test and natural

language descriptor ratings to derive primary factors of personality. Of these factors, he found three that resemble contemporary aspects of openness to experience: Intelligence, Imaginative Emotionality, and Bohemian Intellectualism. Performing a similar study, Fiske (1949) identified five recurring factors with the fourth factor being labeled, "Inquiring Intellect," denoting characteristics that emphasized intellectual curiosity (see chapter ► ["Curiosity"](#)). Later factor analytic studies found that these intellectual characteristics tended to associate with more "culturally refined" qualities such as autonomy and appreciation for aesthetics, leading to a label of "Culture" (Norman 1963; Tupes and Christal 1961/1992).

Since these seminal studies, the conceptualization of openness to experience has continued to expand with studies examining English language adjectives (Goldberg 1981) and behavioral correlates such as hypnotic susceptibility (Tellegen and Atkinson 1974). The culmination of these works formed a consensus label of "Openness to Experience" (Costa and McCrae 1976; Rogers 1954). Costa and McCrae (1978) led this consensus by elaborating on the trait's structural definitions and establishing a broader agreement on the trait's conceptualization (McCrae and Costa 1997). Encompassing this broader definition, open people were described as having "[flexible] boundaries in concepts, beliefs, perceptions, and hypotheses" (Rogers 1954, p. 254) and by "[their] breadth, depth, and permeability of consciousness [(see chapter ► ["Consciousness"](#))], and [their] recurrent need to enlarge and examine experience" (McCrae and Costa 1997, p. 826).

More recent perspectives are centered around these definitions, which is reflected in contemporary self-report inventories. McCrae and Costa's own inventory, the NEO-PI-3 (McCrae et al. 2005), was designed to capture the breadth of the trait using six lower-order facets: actions (openness to new experiences on a practical level), aesthetics (appreciation of art and nature; see chapter ► ["Aesthetics"](#)), fantasy (receptivity to the inner world of imagination; see chapter ► ["Imagination"](#)), feelings (openness to inner

feelings and emotions; see chapter ► “[Emotion](#)”), ideas (intellectual curiosity), and values (readiness to reexamine one’s own values and those of authority figures). Another notable inventory is DeYoung et al. (2007) Big Five Aspects Scale, which breaks openness to experience into two aspects: Openness and Intellect. The Openness aspect (hereafter referred to as Experiencing; Connelly et al. 2014) denotes engagement with aesthetic and perceptual experiences, while the Intellect aspect denotes engagement with semantic and intellectual information. These aspects represent higher-order summaries of the NEO-PI-3’s facets, reflecting separate but related dimensions of openness to experience.

Although a broader consensus has been established in the conceptualization and assessment of openness to experience, there still remains some debate about the taxonomy of the trait – that is, the number and type of characteristics that make up the trait. Connelly et al. (2014) examined this issue using a top-down theoretical sort and meta-analytic approach to identify “core” components of openness to experience that were solely related to openness to experience and “compound” components that were related to openness to experience and other traits. In their study, they identified eleven components: four core (aestheticism, openness to sensations, nontraditionalism, and introspection) and seven compound (openness to emotions, innovation, variety-seeking, fantasy, tolerance, autonomy, and thrill-seeking).

Similarly, Christensen et al. (2019) examined this issue using a bottom-up network analytic approach to identify components from four different openness to experience inventories. They found ten components (aesthetic appreciation, diversity, fantasy, imaginative, intellectual curiosity, intellectual interests, nontraditionalism, openness to emotions, self-assessed intelligence, and variety-seeking), which largely corresponded with Connelly and colleagues’ findings. When taken together, these studies provide a fruitful framework for developing new measures of openness to experience that comprehensively represent its contemporary taxonomy.

Outcomes Related to Openness to Experience

The breadth of characteristics encompassed by openness to experience are associated with nearly every faculty of human psychology – from cognition and memory to perception and emotion to behavioral and psychopathological functioning. Before discussing some of these outcomes, it is important to make clear *who* openness to experience refers to. Although it is common to say that individual people possess openness to experience, it is more appropriate to say that openness to experience is a common dimension of personality that represents “a category for classifying functionally equivalent forms of behavior in a general population of people” (Allport 1961, p. 340). Therefore, when referring to open people, this reference is for a population of people that are higher on characteristics of openness to experience relative to other populations rather than an individual person.

The most researched outcomes of openness to experience are related to cognition. More than any other trait, openness to experience is defined by cognitive characteristics (Zillig et al. 2002). This is perhaps not surprising given the trait’s early links to intelligence, including intelligence being considered a part of the trait (Cattell 1947). Beyond intelligence, open people’s most notable attribute is their tendency to be creative (Oleynick et al. 2017). This association is found in nearly every measure of creativity: divergent thinking (Silvia et al. 2008; see chapter ► “[Divergent Thinking](#)”), creative self-efficacy (Karwowski and Lebuda 2016; see chapter ► “[Creative Mindsets](#)”), creative hobbies (Conner and Silvia 2015), and creative achievements (Kaufman et al. 2016).

One common cognitive thread underlying both creativity and openness to experience is their neural architecture. Both phenomena have been shown to be associated with the functional connectivity between cognitive control (lateral prefrontal and anterior inferior parietal regions) and default mode networks (a set of cortical midline, medial temporal, and posterior inferior parietal regions; Beaty et al. 2015, 2018). These

networks are thought to support executive and associative memory processes, respectively. Further evidence of this cognitive link has been demonstrated in studies examining the associative structure of memory. Both creative and open people are shown to have more interconnected and flexible associations between concepts in their semantic memory, which may allow them to be more cognitively flexible (Christensen et al. 2018; Kenett et al. 2014). Therefore, open people may think and reason about the world differently than less open people.

Open people may not only think about the world differently but also perceive the world differently. There is growing evidence that open people have different reactions to sensory and perceptual stimulus. Early work in this area has focused on *aesthetic chills* or the experience of goose bumps and shivers in response to the arts, which has been denoted as “a universal marker of openness to experience” (McCrae 2007). Open people seem to experience aesthetic chills more often in response to art (Nusbaum and Silvia 2011) and music (Silvia and Nusbaum 2011) than less open people. Awe (see chapter ► “Awe”) is another experience open people often have in response to aesthetic appreciation (e.g., nature and music; Silvia et al. 2015), including being more likely to feel like crying during music that produces awe experiences (Cotter et al. 2018). This seems to suggest that open people often experience a broad range of emotions. This is supported by research demonstrating that open people experience mixed emotional states (i.e., concurrent feelings of positive and negative affect) more often than less open people (Barford and Smillie 2016).

These mixed emotional states sometimes occur with appraisals of visual art, indicating that there’s a connection between cognitive and perceptual processes (Barford et al. 2018). More recent work has demonstrated that open people’s perceptual processing may differ at low levels, suggesting these emotional states may start from the bottom-up (Antinori et al. 2017). Antinori et al. (2017) examined the phenomenon of *binocular rivalry* – when visual perception alternates between stimuli and neither stimuli are fully suppressed – in relation to personality. They

found that open people reported experiencing more binocular rivalry, meaning that open people were more prone to combining perceptual information at a basic level.

This finding is consistent with evidence indicating that open people tend to have a “leakier” filter for preconscious information, which is often referred to as *latent inhibition* (Peterson et al. 2002). Open people are shown to have decreased latent inhibition, meaning they are less likely to ignore stimuli previously experienced as irrelevant, thereby increasing the range of associations for stimuli. These overinclusive associations may come at a cost: seeing meaningful patterns and associations when there are none. This phenomenon is known as *apophenia* and is a prominent feature of psychosis, particularly with positive symptoms of schizophrenia-spectrum disorders (i.e., symptoms that are present that are usually not). Given this connection between openness to experience and overinclusive associations, it is not surprising that there is a positive association between openness to experience and *positive schizotypy* (subclinical to clinical traits of positive schizophrenia-spectrum symptoms; Kemp et al. *in press*).

In DeYoung et al. (2012) Openness/Intellect simplex model, apophenia is at the extreme end of the Openness (Experiencing) aspect. More recent research has expanded on this view, positing a unified framework that places the Experiencing aspect on the same continuum with psychoticism and apophenia (from typical personality variation to psychopathology; Blain et al. 2020). This framework is supported by neurological evidence demonstrating that the shared variance between Experiencing and Psychoticism is linked to increased network coherence in the default mode network and decreased coherence in the cognitive control network (Blain et al. *in press*). This suggests that those who are on the extreme end of the Experiencing continuum may be more psychosis prone.

Possibility and Types of Experience

In this brief review on the outcomes of openness to experience, it should hopefully be clear that

open people's experiences represent a spectrum of cognitive, perceptual, and behavioral possibilities. It is necessary to reiterate that these findings likely do not apply to every individual high on openness to experience but is more representative of the population of highly open people. For individual people, the trait may manifest as types of openness to experience rather than the breadth of the trait.

Take the example of a classic openness to experience archetype: The artist. Kaufman et al. (2016) found that high achieving people in the arts domain tended to be higher on the Experiencing aspect of openness to experience than the Intellect aspect. Certainly, some artists may be more intellectual than others but what characterizes most artists is that they engage with aesthetic and perceptual experiences (DeYoung et al. 2012; see chapters ► [“Possible in Performance and Performing Arts”](#), and ► [“Possible in Visual Arts”](#)). Similarly, they found that high achieving people in the sciences domain tended to be higher on the Intellect aspect of openness to experience than the Experiencing. Once again, some scientists may be more aesthetically inclined than others but they are most notably characterized by their engagement with intellectual experiences (DeYoung et al. 2012).

One type of experience that is scarcely measured in contemporary openness to experience inventories is an openness to sociocultural experiences (but see McCrae 1996 and Woo et al. 2014). In Christensen et al.'s (2019) openness to experience network, they found evidence of an Open-Mindedness aspect, which was defined as “a receptiveness toward others’ ideas, values, beliefs, lifestyles, and culture” (p. 10). There is good reason to suspect that this is an important part of openness to experience types as these people may be more open to cross-cultural experiences such as trying new foods or engaging in local traditions (McCrae 1996; McCrae et al. 2005; Woo et al. 2014). There is some evidence to suggest that having cross-cultural experiences, such as studying abroad in college, may increase people's openness to experience (Martin et al. 2015).

These examples indicate that the types of experiences that people are open to facilitate

different types of possibilities. Being open to other cultures, for example, may facilitate perspective-taking (see chapter ► [“Perspective-taking”](#)) and empathy (see chapter ► [“Empathy”](#)) for those living in different parts of the world. Without that openness, a person could remain closed-off to considering others' circumstances and their worldview may not change. A sense of humor (see chapter ► [“Humor”](#)) is another example: What is a sense of humor without the openness to entertain conflicting worldviews or maintain incompatible social and semantic scripts (Attardo 1994)? Thus, a tendency to be open to an experience is a prerequisite for exploring its possibilities.

Across different types of experience, there are likely common motivational factors, such as curiosity, that contribute to seeking out new possibilities (Kashdan et al. 2018). Indeed, a drive to explore the unknown is fundamental to openness to experience (DeYoung 2013). One person might seek out complex and abstract artwork because it provides an opportunity for personal growth, while another person might be driven towards scientific discovery because they want to know the unknown (Kashdan et al. 2018). When it comes to exploring types of experience, specific characteristics of the trait (e.g., NEO-PI-3 facets) may better explain who is driven towards what (Möttus 2016). Therefore, future research on openness to experience should consider what components of the trait are contributing to the types of experiences and outcomes under study.

Summary

Openness to experience is a complex trait that represents the breadth of human experience. Its definition has become better realized over the years with contemporary models arriving at a clearer consensus. From this consensus, it is apparent that openness to experience captures an openness for all types of human experience: cognitive, perceptual, behavioral, and even sociocultural. Open people not only see the world differently but engage with it differently. Importantly, not all open people are alike, each

having their specific drives and motivations for distinct types of experience. Through these different types of experience, open people engage with the unknown and explore the edges of the possible.

Outsider Writing

Kiene Brillenburg Wurth
Comparative Literature, Utrecht University,
Utrecht, Netherlands

Abstract

Outsider art and writing is usually defined as a form of artistic or literary expression that willingly or unwillingly shuns the public sphere, as it has not been produced for commercial gain and/or public recognition, and testifies to a way of worldmaking that is other and singular, emerging out of a singular experience. This entry argues, however, that the emphasis on otherness and lack in definitions of outsider art or writing no longer holds. Outsider art and writing is just as socially conditioned as “insider” art, albeit possibly *differently* conditioned. Rather than a practice of neurologically or physically divergent creators only, I argue that outsider art or writing is a practice extending beyond professional fields, beyond immediate acclaim, celebrity, and success – whether by choice or by force.

Keywords

Consecration · Sociology of art and culture · Creativity · Neurological divergence · Outsider art · Outsider writing · Singularity · Pierre Bourdieu · Wies Janssen · Judith Scott · Heringa/Van Kalsbeek · Henry J. Darger · Emily Dickinson · Franz Kafka · Robert Walser · Babouillec

When is art, when is literature (Danto)? When do we recognize visual, sculptural, musical, and literary works as “art,” “literature,” or “music”? Is it when they appear in certain galleries and

museums, issued by distinguished publishers, and valued by certain critics and art dealers? When is creativity consecrated – attaining cultural legitimacy – and why (Bourdieu)? When is it not? In the slipstream of Pierre Bourdieu, Arthur Danto, Janice Redway, and others, these questions have framed the sociology of art and literature since the 1970s: the study of the valuation of art and literature in their respective social fields. Such fields, Bourdieu has established long ago, are fields of power, with mechanisms of inclusion and exclusion in place to adopt or marginalize artists and writers (Bourdieu). These power mechanisms – complex, indiscernible, and distributed across a range of cultural actors and institutions – render visual or verbal works possible as “art” or “literature.” The question that I raise here is: When – and why – do visual and verbal works fall outside the range of such possibility? What does visual and verbal creativity amount to in that case? In this entry, I answer these questions by focusing on so-called “outsider” art and writing. I elaborate on the concept of “outsider art,” add the dimension of outsider writing, and offer a few case studies to argue for more inclusive possibilities of “art” and “literature.” I start from the assumption that “art” and “literature” are never-neutral categories shaped in social, historical, and cultural contexts that set standards and determine values.

Amsterdam – the town where I happen to live – hosts a special museum: the *Museum of the Mind/Spirit* [*Geest*, from Germanic *Geist*, meaning both mind and spirit], with an extensive collection of outsider art. The focus of this museum is on works created by artists working with nonnormative abilities: they are physically and/or neurologically divergent. These artists may live in psychiatric institutions, or clinics for longer-term physical care, and/or produce their work in workshops and day-care centers catered to people living in such institutions. Wies Janssen, for instance, is a visual artist whose work is on display in the *Museum of the Mind*. Her work is introduced as being the expression of a “special (also implying: extraordinary) woman” [“een bijzondere vrouw”] (*Museum of the Mind*). Janssen (1954) works at Atelier Covida, a semiprofessional art center

connected to a residential- and day-care center for mentally divergent humans. As an artist, the webpage of the *Museum* stresses, Janssen reflects on moral and social injustice. She has conducted extensive research on WWI and II, seeking to render the loss, grief, and horror generated by these wars “indelible” (*Museum of the Mind*). Her painterly work on these events includes found and embroidered material. These function as indices – palpable traces – that bear witness to Janssen’s minute, persistent, and dedicated research (*Museum of the Mind*). With their striking colors, density, and often huge size, these works affect me accordingly. They are overwhelming, releasing “the past” from abstraction into a reality of things.
